Abstract

Introduction. Primary tumors of the heart are rare, usually benign and occur mostly in adults. The prevalence of these tumors ranges from 0.002 to 0.3% in autopsy series. Usually, these tumors originate from the endocardium, followed by the myocardium and the rarest by the pericardium 1–4. The majority of primary tumors of the heart are benign 4, 5. Papillary fibroelastoma (PFE) accounts for less than 10% of all cardiac tumors, but it is the most common valvular tumor 6–9. The clinical presentation of papillary fibroelastoma varies from asymptomatic cases to cases with severe clinical presentation most likely due to embolic complications. Most PFEs are not discovered during echocardiography or autopsy. We presented a case of PFE of aortic valve accidentally discovered during echocardiography.

Case report

A 53-year-old man underwent routine echocardiographic examination without any other symptoms. He had been treated for hypertension five years. Echocardiography found a round tumor with the diameter of 13 mm attached with 6 mm length pedicle to the noncoronary cuspis of the aortic valve. The tumor was surgically removed and pathohistological examination confirmed diagnosis of papillary fibroelastoma. After surgery the patient fully recovered without tumor recurrence or aortic regurgitation.

Conclusion. Histologically, papillary fibroelastoma is benign tumor of the heart. As demonstrated in this case, a papillary fibroelastoma can be an incidental finding discovered during echocardiography in patients with the history of hypertension.

Introduction

Primary tumors of the heart are rare, usually benign, and occur mostly in adults. The prevalence of these tumors ranges from 0.002 to 0.3% in autopsy series. Usually, these tumors originate from the endocardium, followed by the myocardium and the rarest by the pericardium 1–4. The majority of primary tumors of the heart are benign 4, 5. Papillary fibroelastoma (PFE) accounts for less than 10% of all cardiac tumors, but it is the most common valvular tumor 6–9. The clinical presentation of papillary fibroelastoma varies from asymptomatic cases to cases with severe clinical presentation most likely due to embolic complications. Most PFEs are not discovered during echocardiography or autopsy. We presented a case of PFE of aortic valve accidentally discovered during echocardiography.

Case report

A 53-year-old man underwent routine echocardiographic examination without any other symptoms. He had been treated for hypertension five years. Echocardiography found a round tumor with the diameter of 13 mm attached with 6 mm length pedicle to the noncoronary cuspis of the aortic valve. The tumor was surgically removed and pathohistological examination confirmed diagnosis of papillary fibroelastoma. After surgery the patient fully recovered without tumor recurrence or aortic regurgitation.
aortic valve. The tumor was mobile, round, with echo dense and well-demarcated borders (Figure 1). The tumor did not cause any aortic insufficiency.

The patient immediately underwent surgery because of the high risk of embolic complication. The removed tumor was round, soft, grayish, with the diameter of 13 mm. Histopathologic examination showed that the tumor was of papillary configuration. The papillary cord, being an elastic fiber, was surrounded by a mucous layer without blood vessels and covered by a layer of flattened cells. Based on these characteristics, the diagnosis of PFE was made (Figures 2 and 3).

Discussion

Tumors of the heart are rare with the prevalence for primary tumors from 0.002% to 0.3% discovered on autopsy. The three quarters of heart tumors are benign. The most common primary benign cardiac tumor is myxoma, while PFEs account for less than 10% of these tumors. The most frequent sites of their occurrence are the aortic or mitral valves. In some cases PFE was found in other parts of the heart such as the left ventricle or the atrial septum.

PFE occurs occasionally, usually in middle-aged and older patients, with a slightly higher incidence in males. Xu et al. described a case of PFE of the tricuspid valve in a 1-month-old child. At the time of diagnosis PFE is usually a small tumor with papillary structures of collagen deposits, elastic material and proteoglycans.

To date it remains unclear whether this tumor is true neoplasm, hamartomatous proliferation or organized thrombus. Based on the presence of dendritic cells and cytomegalovirus in some patients some authors propose that PFE can be associated with viral endocarditis. De Feo et al. reported a possibility of exposure to environmental pollution with the development of PFE.

Most patients with PFE have no symptoms and the tumors in these patients were incidentally diagnosed on echocardiography, catheterization, cardiac surgery or autopsy. PFE is benign tumor but in some patients torn apart parts of the tumor may lead to embolic complications. Stroke, transient ischemic attack, angina, myocardial infarction or sudden death were the most serious complications described, embolism with parts of the tumor, being main reason for the early diagnosis of PFE to be of major interest. Interestingly, valve dysfunction is rarely described, although the tumor is usually located on it.

Due to the risk of treatment complication, usually surgical excision of the tumor, it is done in either symptomatic and asymptomatic patients. Patients with tumor size more

Fig. 1 – Echocardiography (parasternal long axis view) demonstrates a pedunculates mass of 13 mm in size attached to the aortic valve (black arrow).

Fig. 3 – The papillary tumor with hyalinized collagenous matrix encountered by uniform single-layer cells without any blood vessel (HE, ×100).
than 1 cm, as in the presented case, should be surgically treated by tumor excision due to increased risk of embolization and sudden cardiac death.\(^\text{24, 25}\) Asymptomatic patients with nonmobile tumor smaller than 1 cm can be closely followed-up with echocardiography until symptoms develop or tumors enlarges and becomes mobile, and after that tumor could be surgically removed\(^\text{15, 22}\). Patients who from other reasons are not candidates for surgical treatment should be treated with long-term anticoagulation therapy.

**Conclusion**

Papillary fibroelastomas are histologically rare benign cardiac tumors. Although benign due to their structure and localization these tumors can cause serious embolic complications and sudden cardiac death. Surgical removal of tumors is the best way to prevent possible complications. As demonstrated in this case, papillary fibroelastoma can be an incidental finding in echocardiography.
