Abstract

Background/Aim. Sleep is prompted by natural cycles of activity in the brain and consists of two basic states: rapid eye movement (REM) sleep and non-rapid eye movement (NREM) sleep. REM sleep behavior disorder (RBD) is characterized by violent motor and vocal behavior during REM sleep which represents dream enactment. The normal loss of muscle tone, with the exception of respiratory, sphincter, extra ocular and middle ear muscles, is absent in patients with RBD. The origin of RBD is frequently unknown, but can be associated with degenerative neurological disorders, such as Parkinson’s disease (PD). PD patients do not necessarily express features of RBD, which is identified in approximately third to a half of them. The aim of this study was to estimate the prevalence of RBD in a cohort of PD patients, as well as to identify risk-factors for its development. Methods. In the period from December 2010 to September 2011 we recruited 97 consecutive PD outpatients, treated in the Institute of Neurology, Clinical Center of Serbia, Belgrade. After establishing the diagnosis, all the patients filled out a specially constructed questionnaire with the following items: actual age, sex, age at disease onset, disease duration, form of the disease, type of treatment, duration of treatment, the presence of constipation, lessening of smell sense, and family history of PD. At entering the study, patients disability was scored using the Unified Parkinson’s Disease Rating Scale (motor part – UPDRS). Cognitive abilities were assessed by the Mini Mental Status Examination (MMSE) scale, and depression symptoms by the 21-item Hamilton Depression Rating Scale (HDRS). The patients with PD were dichotomized to those with and without RBD using the RBD Questionnaire – Hong Kong (RBDQ-HK) in the manner of an interview. Forms of PD, mode of treatment, sex, constipation and family history were investigated using the Fishers χ² test. Symptoms and treatment duration, the presence of smell disturbances, MMSE score, UPDRS motor score and HDRS score were analyzed by implementation of the Z-test. Actual age and age at disease onset were evaluated by the unpaired t-test. Results. The RBD-positive group contained 15 (15.5%) patients, while in the rest of them (82/97), RBD was not identified (non-RBD group). There was no difference between the two groups considering gender distribution (p = 0.847), age (p = 0.577), age at disease onset (p = 0.141), duration of PD (p = 0.069), family history (p = 0.591), type of initial symptoms (p = 0.899), constipation (p = 0.353), olfaction (p = 0.32) and MMSE scores (p = 0.217). The duration of treatment in the RBD group was longer than in the non-RBD group (9.4 ± 5.3 and 6.3 ± 3.9 years, respectively; p = 0.029), and the UPDRS motor score in the RBD group was higher (19.1 ± 9.4 and 12.7 ± 8.2, respectively; p = 0.013). Also, HDRS scores were higher in patients expressing RBD (10.1 ± 6.0 and 6.4 ± 4.5, respectively; p = 0.019). Conclusion. We found that 15.5% of the consecutive PD patients had RBD, and that the patients with RBD differed from the non-RBD ones regarding duration of treatment, disease and depressive symptoms severity.

Key words: parkinson disease; sleep, rem; sleep disorders; prevalence; risk factors.

Bolesnici sa PB ne moraju uvek ispoljiti odlike koje prate RBD, ko- je se identifikuje kod približno jedne trećine do jedne polovine ovih bolesnika. Metode. U periodu od decembra 2010. do septembra 2011. ambulantno smo pregledali 97 bolesnika sa PB, lečenih u Institutu za neurologiju Kliničkog Centra Srbije u Beogradu. Nakon što je ustanovljena dijagnoza, svi bolesnici popunili su posebno konstruisani upitnik sa sledećim varijablama: starost, pol, godine trajanja bolesti, prisustvo određenih simptomata, test MMSE i HDRS. Rezultati. RBD-positivni grupa uključivala je 15 (15.5%) pacijentkinju, dok je RBD ne pronađeno u ostalim (82/97) pacijentkinjama. Ne postojalo je statistički značajno razlika između dva grada u seoskoj distribuciji (p = 0.847), u starosti (p = 0.577), u starosti kod početka bolesti (p = 0.141), dužinom trajanja bolesti (p = 0.069), rodinom historijom (p = 0.591), tipom prvih simptoma (p = 0.899), konstipacijom (p = 0.353), olfaktorijom (p = 0.32) i MMSE ocenom (p = 0.217). Dužina trajanja bolesti u RBD grupi je bila duža od u ne-RBD grupi (9.4 ± 5.3 i 6.3 ± 3.9 godina, istodobno; p = 0.029), dok je motorni del UPDRS u RBD grupi bio veće (19.1 ± 9.4 i 12.7 ± 8.2, istodobno; p = 0.013). Takođe, HDRS ocene su bile veće kod pacijenata izrazila RBD (10.1 ± 6.0 i 6.4 ± 4.5, istodobno; p = 0.019). Conclusion. Nismo nudeo da 15.5% od konsekutivnih PD pacijenata imaju RBD, a pacijenti sa RBD su se razlikovali od ne-RBD oni prilikom dužine trajanja bolesti, bolesti i depresivnih simptoma.

Ključne riječi: bolest Parkinsona; snabdaje; rem snabdaje; prevalencija; rizik faktori.
(UPDRS). Kognitivne sposobnosti procenjivane su pomoću skale Mini Mental Status Examination (MMSE) (Mini mental test), a simptomati depresije bodovanim su uz pomoć skale Hamilton-ove Depressi-

tion Rating Scale (HDRS). Bolesnici sa PB podijeljeni su na one sa i bez RBD koristeći RBD Questionnaire – Hong Kong (RBDQ-HK) upit-
nik u vidu interjua. Forma PB, način lečenja, pol, opstipacija i po-

rodičina anamneza PD su statistički računate Fišerovim \( \chi^2 \) testom. Dužina trajanja simptoma i lečenja, prisustvo olfaktivnih promena, MMSE skor, UPDRS skor i HDRS skor analizirani su primenom Z-testa. Starost i godine života na početku bolesti procenjene su neuparanim \( t \)-testom. Rezultati. RBD pozitivnu grupu činilo je 15 (15,5%) bolesnika, dok kod ostalih (82/97) RBD nije bio identifi-
kovan. Između RBD pozitivne i negativne grupe kada je u pitanju pol (\( p = 0,847 \)), starost (\( p = 0,377 \)), uzrast na početku bolesti (\( p = 0,141 \)), dužine trajanja bolesti od pojavlj simptoma (\( p = 0,069 \)), porodična anamneza (\( p = 0,391 \)), forma bolesti (\( p = 0,899 \)), prisust-
tva opstipacije (\( p = 0,353 \)), smanjenje čula mirisa (\( p = 0,32 \)) i MMSE skor (\( p = 0,217 \)) nije bilo razlike. Dužina trajanja lečenja u grupi RBD pozitivnih bila je značajno duža nego u grupi RBD ne-
gativnih (\( 9,4 \pm 5,3 \) i \( 6,3 \pm 3,9 \) godina, respektivno; \( p = 0,029 \), što je utvrđeno i za UPDRS motorni skor (\( 19,1 \pm 9,4 \) i 12,7 \pm 8,2, res-
pективно; \( p = 0,013 \)). Takođe, HDRS skor bio je viši kod bolesnika kod kojih je utvrđen RBD, za razliku od bolesnika u grupi u kojoj je ovo oboljenje bilo odsutno (\( 10,1 \pm 6,0 \) i 6,4 \pm 4,5, respektivno; \( p = 0,019 \)). Zadužen. Dobijeni rezultati pokazuju da 15,5% bole-
snika sa PB ima i RBD, kao i da se bolesnici sa RBD razlikuju od onih bez tog oboljenja po dužini trajanja lečenja, težini bolesti (ut-

vorenj UPDRS skorom) i težini depresivnih simptoma.

**Introduction**

Sleep is prompted by natural cycles of activity in the brain and consists of two basic states: rapid eye movement (REM) sleep and non-rapid eye movement (NREM) sleep, which consists of stages N 1 through 3 \(^1\). Intense dreaming occurs during REM sleep as a result of heightened brain activity, and those without RBD, by using the RBD Questionnaire – Hong Kong (RBDQ-HK) \(^12\) in the manner of an interview. The questionnaire comprises 13 queries with a score ranging from 0 to 100. The questions considered various clinical fea-
tures of RBD defined by the International Classification of Sleep Disorders \(^13\) (ICSD-II) and derived from clinical ob-
servations by the authors of the questionnaire and previous empirical work (i.e. frequent dreams, frequent nightmares, emotional, violent or aggressive or frightening dreams, disturbed sleep, sleep talking, shouting or yelling in sleep, dream-related movements, falling out of bed, sleep-related injuries (SRI), attempts to assault/injure and SRI related to dream content). The cut-off score for disproving/proving RBD was 18/19.

The forms of PD, mode of treatment, sex, constellation and family history were investigated using the Fishers \( \chi^2 \) test. Symptoms and treatment duration, the presence of smell disturbances, MMSE score, UPDRS motor score and HDRS scores were compared between the RBD positive and negative groups. Cognitive abilities were assessed by the Mini Mental Status Examination (MMSE) scale \(^10\), while depressive symptoms by the 21-item Hamilton Depression Rating Scale (HDRS) \(^11\).

The patients with PD were dichotomized to those with and those without RBD, by using the RBD Questionnaire – Hong Kong (RBDQ-HK) \(^12\) in the manner of an interview. The questionnaire comprises 13 queries with a score ranging from 0 to 100. The questions considered various clinical features of RBD defined by the International Classification of Sleep Disorders \(^13\) (ICSD-II) and derived from clinical ob-
servations by the authors of the questionnaire and previous empirical work (i.e. frequent dreams, frequent nightmares, emotional, violent or aggressive or frightening dreams, disturbed sleep, sleep talking, shouting or yelling in sleep, dream-related movements, falling out of bed, sleep-related injuries (SRI), attempts to assault/injure and SRI related to dream content). The cut-off score for disproving/proving RBD was 18/19.

The forms of PD, mode of treatment, sex, constellation and family history were investigated using the Fishers \( \chi^2 \) test. Symptoms and treatment duration, the presence of smell disturbances, MMSE score, UPDRS motor score and HDRS scores were compared between the RBD positive and negative groups. Cognitive abilities were assessed by the Mini Mental Status Examination (MMSE) scale \(^10\), while depressive symptoms by the 21-item Hamilton Depression Rating Scale (HDRS) \(^11\).

---

**Methods**

Between December 2010 and September 2011 we re-

ruited 97 consecutive PD outpatients treated in the Institute of Neurology, Clinical Center of Serbia, Belgrade, who gave informed and written consent for their participation. The study was approved by the Ethical Committee of our institu-

tion.

Only patients who fulfilled the Brain Bank criteria for clinical diagnosis of PD \(^6\) were included. After establishing the diagnosis, all the patients filled out a specially con-

structed questionnaire with the following items: actual age, sex, age at disease onset, disease duration, form of the disease \(^7\) (tremor predominant or rigidity predominant), type of treatment, duration of treatment, the presence of constipa-

tion, lessening of smell sense (quality of olfaction, i.e. hy-

posmia and/or anosmia, was assessed using the Pocket Smell test (PST) \(^8\) and anamnestic data concerning common etiolo-
gies of possible lessening or absence of smell), and family history of PD. At the study entry, patients disability was scored using the Unified Parkinson’s Disease Rating Scale (motor part) (UPDRS) \(^9\). Cognitive abilities were assessed by the Mini Mental Status Examination (MMSE) scale \(^10\), while depressive symptoms by the 21-item Hamilton Depression Rating Scale (HDRS) \(^11\).

The patients with PD were dichotomized to those with and those without RBD, by using the RBD Questionnaire – Hong Kong (RBDQ-HK) \(^12\) in the manner of an interview. The questionnaire comprises 13 queries with a score ranging from 0 to 100. The questions considered various clinical features of RBD defined by the International Classification of Sleep Disorders \(^13\) (ICSD-II) and derived from clinical ob-
servations by the authors of the questionnaire and previous empirical work (i.e. frequent dreams, frequent nightmares, emotional, violent or aggressive or frightening dreams, disturbed sleep, sleep talking, shouting or yelling in sleep, dream-related movements, falling out of bed, sleep-related injuries (SRI), attempts to assault/injure and SRI related to dream content). The cut-off score for disproving/proving RBD was 18/19.

The forms of PD, mode of treatment, sex, constellation and family history were investigated using the Fishers \( \chi^2 \) test. Symptoms and treatment duration, the presence of smell disturbances, MMSE score, UPDRS motor score and HDRS scores were compared between the RBD positive and negative groups. Cognitive abilities were assessed by the Mini Mental Status Examination (MMSE) scale \(^10\), while depressive symptoms by the 21-item Hamilton Depression Rating Scale (HDRS) \(^11\).

---

Results

The cohort comprised of 41 female and 56 male subjects. The mean age of our patients was 62.1 ± 8.8 years, with the age at disease onset 54.3 ± 9.4 years. The duration of symptoms was 8.3 ± 4.9 years. Concerning the form of the disease by which the symptoms first manifested themselves, 59 (60.8%) of the patients had the tremor-predominant form, 37 (38.1%) akinetic-rigid form, while only 1 (1%) of the patients presented with mixed symptoms. The duration of treatment was 6.8 ± 4.3 years, with levodopa as the most frequently used drug. Other centrally active medications included levodopa, amantadine, ropinirole, clonazepam, pramipexole, diazepam, clozapine, alprazolam, lorazepam, fluoxetine, and selegiline. Therapy-wise, 11 (11.3%) of the patients had undergone monotherapy, while 86 (88.7%) used more than one medication (polytherapy). In regards to constipation, 62 (63.9%) of the patients had, and 35 (36.1%) of them did not have this symptom. The sense of smell was normal, reduced or absent in 11 (11.3%), 19 (19.6%) and 67 (69.1%) of the examinees, respectively. A family history of PD was positive in 6 (6.2%), negative in 87 (89.7%), and unknown in the rest of the patients – 4 (4.1%). The MMSE score was 27.5 ± 2.9, without detailed neurophysiological studies. Briefly, the patients with RBD did not differentiate from the non-RBD patients according to sex, age, age at disease onset, duration of symptoms, family history, form of the disease, constipation, olfaction, mode of treatment and MMS, but they were statistically different regarding duration of treatment, disease severity and the presence of depression.

Discussion

In this study we detected RBD in 15.5% of the patients with PD, using RBDQ-HK, without detailed neurophysiological studies. Briefly, the patients with RBD did not differentiate from the non-RBD patients according to sex, age, age at disease onset, duration of symptoms, family history, form of the disease, constipation, olfaction, mode of treatment and MMS, but they were statistically different regarding duration of treatment, disease severity and the presence of depression.

Our results are quite similar to the results of Vibha et al., with the prevalence of RBD of 19.4% in their PD cohort, and Comella et al., whose estimates were even closer (15%). Overall, the reported prevalence of RBD in PD population varies from 15 to 60%, most probably due to different methods of patient selection and disorder ascertainment (spouses’ interview, nocturnal video, etc.)

Cross-sectional studies failed to find the difference in

There was no difference between the two groups considering gender distribution (p = 0.847), age (p = 0.577), age at disease onset (p = 0.141), duration of PD (p = 0.069), family history (p = 0.591), type of initial symptoms (p = 0.899), constipation (p = 0.353), olfaction (p = 0.32) and MMSE scores (p = 0.217).

The duration of treatment in the RBD group was longer than in the non-RBD group (6.4 ± 3.9 years, respectively; p = 0.029), and the UPDRS motor score in the RBD group was higher (12.7 ± 8.2, respectively; p = 0.013). Also, HDRS scores were higher in the patients expressing RBD (10.4 ± 6.4 vs. 6.4 ± 4.5, respectively; p = 0.019).

REM – rapid eye movement; MMSE – Mini Mental State Examination; UPDRS – Unified Parkinson’s Disease Rating Scale; HDRS – Hamilton Depression Rating Scale; RBDQ-HK – REM Sleep Behavior Disorder Questionnaire–Hong Kong; *statistically significant.
age at disease onset between RBD and non-RBD PD patients. In our study, initial Parkinson’s disease symptoms started earlier in the patients with RBD than in those without RBD, but the observed difference did not reach statistical significance.

In contrast with our and the study of Arnulf, other authors reported a striking male predominance in chronic RBD patients. In the first series of RBD patients described in 1985 by Schenck et al., more than 90% of them were males. Other studies also found male predominance (87% and 83.3%) in PD patients with RBD, as opposed to those without this sleep disorder. Lack of association of RBD to any type of PD we found in our study was in accordance with the data obtained from a larger cohort of PD patients.

Concerning family history, no difference was obtained between the RBD and non-RBD groups of PD patients, in accordance to previous reports. Lack of difference was also noted for constipation and olfactory function.

We assessed cognition with robust instrument, MMSE, and found no statistically significant difference between RBD and non-RBD group. However, some cross-sectional studies gave evidence of mild cognitive impairment in PD patients with RBD, as opposed to those without this sleep disorder (the instrument we used was not sensitive enough to detect mild cognitive impairment in our patients). In a study of PD patients with RBD progression to dementia was documented in 48% of them during a period of 4 years, compared to none in the non-RBD group.

Cognition was lower in PD patients with RBD than those without it. Also, the existence of RBD had strong anticipatory value for the development of hallucinations over a 12-year follow-up. However, careful follow-up is needed for a suggestion that the presence of RBD predisposed patients for developing dementia.

Contrary to some previous data, the presence of RBD in PD in our study correlated with the disease severity (UPDRS motor scores), and HDRS scores. Also, the longer the treatment of PD patients was, the chances they had to develop RBD were larger. Our data are in partial accordance with several cross-sectional studies where RBD was associated with older age, longer disease duration, higher Hoehn and Yahr score, lower amplitude of response to their medication, more frequent falls, more fluctuations, more psychiatric comorbidity, and higher doses of levodopa. A population-based prevalence study that evaluated 231 PD patients for RBD during a follow-up period of 8 years found an increased prevalence of probable RBD from 14.6% to 27% during the study period.

In our work, definitive validation of RBD in the patient cohort remains with the RBD-HK questionnaire. A larger number is needed in order to yield more precise results, which would make this the main limitation of our study.

Behaviors during RBD were complex and sometimes dramatic. They included arm and leg movements (93.3%), falling out of bed (20%), assaulting the bed-partner (26.6%) etc., and occasionally resulted in trauma of the patient or the partner (26.6%). In some patients violent behavior was associated with variable forms of vocalization (93.3%). Finally, all of our patients remembered the content of dreams.

Conclusion

In our study, we found that 15.5% of the consecutive PD patients had RBD, and that the patients with RBD differed from the non-RBD ones regarding duration of treatment, disease and depressive symptoms severity.
