Accepted manuscripts are the articles in press that have been peer reviewed and accepted for publication by the Editorial Board of the Vojnosanitetski Pregled. They have not yet been copy edited and/or formatted in the publication house style, and the text could still be changed before final publication.

Although accepted manuscripts do not yet have all bibliographic details available, they can already be cited using the year of online publication and the DOI, as follows: article title, the author(s), publication (year), the DOI.

Uterus Didelphys associated with Endometriosis
Abstract

Introduction. Uterus didelphys results when mullerian duct fusion is completely arrested during development. We presented a rare case of nonobstructive uterus didelphys occurring simultaneously with an endometriotic cyst of the ovary. Case report. A twenty-nine-year-old, nulliparous patient was admitted to our clinic for laparoscopic treatment of an endometriotic ovarian cyst. Diagnoses of right ovarian endometriotic cyst and nonobstructed uterus didelphys were established with bimanual pelvic exam and two-dimensional transvaginal ultrasound. Diagnoses were subsequently confirmed by laparoscopy and magnetic resonance imaging. Laparoscopic incision and drainage of the endometriotic cyst were performed, followed by biopsy and coagulation of endometriotic lesions. Histopathology confirmed ovarian endometriosis. Gonadotropin-releasing hormone analogue (GnRHa) was prescribed postoperatively, for a total of three months. Ten months after completion of treatment, the patients without disease recurrence.

Conclusion: Nonobstructive uterus didelphys is rarely associated with ovarian endometriosis.

Keywords: uterus didelphys, ovarian endometriosis, laparoscopy, infertility

Apstrakt

Zaključak. Dvostruka materica neobstruktivnog tipa je retko udružena sa endometriozom jajnika.

Ključne reči: dvostruka materica, endometrioza jajnika, laparoskopija, infertilitet
Introduction

Mullerian duct anomalies arise as a result of duct development failure, incomplete duct fusion or canalization, or incomplete reabsorption of medial uterine septum. The prevalence of female genital tract anomalies in the general population varies from 0.5% to 5.0% \(^1\). Uterus didelphys arises due to complete failure of Mullerian ducts to fuse and differentiate to form a uterus and cervix during the 8\(^{th}\) gestational week. This is a lateral fusion defect of the Mullerian ducts resulting in symmetrical nonobstructive uterus didelphys accompanied by a complete longitudinal vaginal septum \(^2\). Most women with a nonobstructive uterus didelphys are asymptomatic, but some present with dysmenorrhea or dyspareunia in the presence of a longitudinal vaginal septum. If hemivaginal obstruction is present, symptoms tend to occur, and include hematocolpos, hematometra, hematometrocolpos, as well as a lower abdominal pain \(^3\). Uterus didelphys, without an obstructed hemivagina, is rarely associated with endometriosis. Endometriosis is more commonly present in the obstructive forms of uterus didelphys. Uterus didelphys has also been described as being part of a Herlyn-Werner-Wunderlich syndrome (HWWS), also known as obstructed hemivagina and ipsilateral renal agenesis (OHVIRA syndrome) \(^4,5\). Majority of cases of nonobstructive uterus didelphys do not require surgical management. Excision of vaginal septum is indicated in obstructed unilateral vagina, while a hemihysterectomy is indicated in rare cases of cervical hypoplasia or agenesis \(^6,7\).

Case report

A twenty-nine-year-old nulliparous woman was referred to our clinic from a primary healthcare centre for laparoscopic surgery of a right ovarian endometriotic cyst. Gynecologic history revealed that menarche occurred at the age of 14 years, and that menstrual cycles have been regular since. The patient has been married for four years, but has failed to become pregnant despite trying in the last two years. Obstetric history revealed a nulligravida. The patient denied a history of previous gynecologic disease. Upon admission to our clinic, a complete preoperative work-up was performed, including a bimanual pelvic exam and two-dimensional transvaginal pelvic ultrasound. Bimanual pelvic exam revealed a partial longitudinal septum in the superior third of the vagina. The double cervix was 1.5 cm long, and contained openings to two endocervical canals. Two separate, firm and mobile pelvic masses were palpable, each mass the size of a small female fist. The left adnexa were mobile and non-tender to palpation. The right ovary was
enlarged and tense on palpation. Two-dimensional transvaginal pelvic ultrasound revealed the following: Two completely separate and equal hemiuteri. The right hemiuterus was antverted, measuring 48x33 mm, was characterized by normal contours and an endometrial thickness of 6 mm. The left hemiuterus was antverted, measuring 50x33 mm, was characterized by normal contours and an endometrial thickness of 6 mm. A right ovarian cyst filled with viscous fluid was seen, and measured 42x40 mm. The left ovary measured 32x24 mm, and contained multiple follicles, which measured up to 6 mm. Double uterine cervix had two endocervical canals, and measured 28 mm in length.

Abdominal and urinary system ultrasound revealed normal findings. Both kidneys were of normal size, morphology and were in their typical location. After preoperative work-up and preparation, the patient underwent laparoscopy. The following were the laparoscopic findings: Two uteri of equal sizes were visualized in the pelvic cavity, each equivalent to the size of a small female fist. The two were completely separate, at a distance of approximately 3-4 cm from each other. Each uterus was associated with one Fallopian tube, and Fallopian tubes were of normal length with mobile fimbria. An endometriotic cyst containing hemorrhagic debris was visualized on the right ovary and measured 40x40 mm. The left ovary was of normal size, morphology and whitish in colour. The laparoscopic finding is shown in Figure 1. The isthmus of the posterior uterine wall of the right hemiuterus had a subserous fibroid, which measured 1 cm. Endometriotic implants were seen on the right uterosacral ligament. As cystectomy, which would encompass complete excision of the cyst and its pseudocapsule, was technically difficult to perform, incision and drainage of the cyst was done instead, followed by biopsy and coagulation of endometriotic lesions. The subserous fibroid was excised. Both specimens were sent for histopathological analysis. Chromopertubation, using methylene blue dye, was performed to assess tubal patency; spillage of the dye from the right tube into the abdomen indicated the patency of the right tube, while the left tube filled up without spillage and was determined to be occluded at the uterine horn. Postoperative recovery was uneventful. The patient was discharged from the hospital on the second postoperative day. Pelvic MRI with paramagnetic contrast was performed postoperatively. MRI findings confirmed a uterus didelphys, which consisted of two non-communicating uterine cavities and two cervices. A partial septum was found in the proximal third of the vagina. Magnetic resonance image is shown in Figures 2. The final histopathological diagnosis included the following:
Endometriotic cyst of the right ovary; uterine fibroid. The histopathological finding is shown in Figure 3. The patient was managed with suppressive therapy using a Gonadotropin-releasing hormone analogue (GnRHa), triptorelin (Dipherelin 3.75 mg), administered every 28-30 days for a total of three months. The patient complied with all three cycles of treatment. Follow-up pelvic ultrasound and CA-125 levels were performed and were within normal reference range. The patient felt well and did not manifest signs of recurrent disease.

**Discussion**

Uterine malformations are a result of failure of Mullerian duct development, fusion, canalization or reabsorption. The prevalence of uterine anomalies in the unselected general population was 5.5%, compared to 8.0% in a population of infertile women, 13.3% in women with a history of miscarriage and 24.5% in those with miscarriage and infertility. Multiple classification systems are used to classify female genital tract anomalies. The classification systems include the following: American Society of Fertility and Sterility (AFSS); American Society of Reproductive Medicine (ASRM); European Society for Human Reproduction and Embryology (ESHRE) and European Society for Gynecologic Endoscopy (ESGE). Uterus didelphys constitutes 11% of all uterine malformations. Uterus didelphys arises when Mullerian ducts completely fail to fuse leading to two separate uterine cavities and two cervices. Each hemiuterus is associated with one Fallopian tube. There may be a single or double vagina. A partial or complete longitudinal septum is present in 75% of the cases. Uterus didelphys has been described as part of the Herlyn-Werner-Wunderlich syndrome (HWWS), which is also known as obstructed hemivagina and ipsilateral renal agenesis (OHVIRA). Uterus didelphys without an obstructed hemivagina is rarely associated with endometriosis. In the literature, there are reports of individual cases of nonobstructive uterus didelphys associated with ovarian endometriosis or peritoneal endometriosis. We presented a patient with a uterus didelphys consisting of two completely separate uterine cavities and two cervices, as well as a partial septum in the proximal third of the vagina, and a right ovarian endometriotic cyst. Our hypothesis is that endometriosis of the right ovary developed as a result of retrograde menstruation through the right Fallopian tube. This hypothesis is supported by the findings of chromopertubation during laparoscopy, which indicated that the right tube was patent, while the left tube was obstructed at the uterine horn. Endometriosis is more commonly present in the obstructive forms of uterus didelphys. Uterus didelphys with cervical
agenesis is often associated with adenomyosis and ovarian endometriosis. Pelvic endometriosis was present in 19.15% of patients with HWWS. Ipsilateral ovarian endometriosis develops almost always in cases of hemivaginal obstruction. Pelvic endometriosis is more frequent in women with complete hemivaginal obstruction and is found in 37% of cases, than in women with incomplete hemivaginal obstruction where it is found in 11.9%. Endometriosis was found in 13.8% of women with OHVIRA, and 5.75% of these cases consisted of ovarian endometriosis. The correlation between Mullerian duct anomalies and infertility is debatable. Mullerian duct anomalies occur in 3.4% of infertile women, while this prevalence increases to 4.3% in the general population, which implies that these anomalies do not negatively influence fertility. Researchers report that women with a uterus didelphys have had twin pregnancies, which developed normally within each of the uteri. A term pregnancy delivered vaginally has been described in the literature. Most women with a nonobstructive uterus didelphys do not manifest any symptoms. If a thick longitudinal vaginal septum is present, common symptoms include dyspareunia and dysmenorrhea. Hematocolpos and hematometra arise as a result of an obstructed vaginal septum, leading to lower abdominal pain. Herlyn-Werner-Wunderlich syndrome is rare and occurs in 0.1% to 3.8% of cases. Hematocolpos and hematometra develop ipsilaterally to the atretic hemivagina. This classical presentation occurs in 72.4% of HWW syndrome cases, while a rare variant of HWW syndrome occurs in 27.6% consisting of a uterine septum and cervical agenesis. The diagnosis of uterus didelphys is usually established by bimanual pelvic exam, pelvic ultrasound (2D and 3D), hysterosalpingography, laparoscopy, hysteroscopy and magnetic resonance imaging. Women with a nonobstructive uterus didelphys usually do not require surgical management. Excision of vaginal septum is indicated in women with an obstructed unilateral vagina. Hemihysterectomy is indicated in cases of uterus didelphys associated with unilateral cervical aplasia.

**Conclusion**

Nonobstructive uterus didelphys is rarely associated with ovarian endometriosis. Most women with a nonobstructive uterus didelphys do not manifest any symptoms. If a thick longitudinal vaginal septum is present, common symptoms include dyspareunia and dysmenorrhea. Endometriosis is more frequently associated with obstructive uterus didelphys, which manifests as hematocolpos and hematometra.
