A GENERAL STRONG NYMAN–BEURLING CRITERION FOR THE RIEMANN HYPOTHESIS

Luis Báez-Duarte

Communicated by Aleksandar Ivić

Abstract. For each \( f : [0, \infty) \to \mathbb{C} \) formally consider its Müntz transform 
\[
g(x) = \sum_{n \geq 1} f(nx) - \frac{1}{x} \int_0^\infty f(t)dt.\]
For certain \( f \)'s with both \( f, g \in L^2(0, \infty) \) it is true that the Riemann hypothesis holds if and only if \( f \) is in the \( L^2 \) closure of the vector space generated by the dilations \( x \mapsto g(kx), \ k \in \mathbb{N} \). Such is the case for example when \( f = \chi_{(0,1]} \) where the above statement reduces to the strong Nyman criterion already established by the author. In this note we show that the necessity implication holds for any continuously differentiable function \( f \) vanishing at infinity and satisfying 
\[
\int_0^\infty t |f'(t)| dt < \infty.
\]
If in addition \( f \) is of compact support, then the sufficiency implication also holds true. It would be convenient to remove this compactness condition.

1. Introduction

1.1. Preliminaries and notation. The Riemann hypothesis shall be abbreviated as RH. We denote \( L_p := L_p(0, \infty) \), and, likewise we use \( C_0, C_{00} \) to denote, respectively, the space of continuous functions on \([0, \infty)\) vanishing at infinity, and its subspace of compactly supported functions, whereas \( C^1_0, C^1_{00} \) denote their corresponding subspaces of continuously differentiable functions.

We let \( \chi := \chi_{(0,1]} \) be the characteristic function of \((0, 1]\), and \( \rho(x) := x - \lfloor x \rfloor \) the fractional part of \( x \). We set \( \rho_1(x) := \rho(1/x) \). Note that \( \rho_1 \in L_p \) for \( 1 < p \leq \infty \).

For each \( \lambda > 0 \) the dilation \( K_\lambda \) defined on functions \( f : [0, \infty) \to \mathbb{C} \) is given by 
\[
K_\lambda f(x) := f(\lambda x).\]
\( K_\lambda \) is a bounded operator on any \( L_p, 1 \leq p \leq \infty \).

For any \( g : [0, \infty) \to \mathbb{C} \) define \( \mathcal{B}(g) \) to be the linear hull of \( \{ K_n g : n \in \mathbb{N} \} \). Obviously, if \( g \in L_p \), then \( \mathcal{B}(g) \subset L_p \).

2000 Mathematics Subject Classification: Primary 11M26.
Key words and phrases: Riemann zeta-function, Riemann hypothesis, strong Nyman–Beurling theorem, Müntz's formula.

This work is extracted from our preprint “Thoughts on The Riemann hypothesis, 34 v.2” of 7 June 2004.
The Mellin transform of $f$ at $s \in \mathbb{C}$, denoted $\hat{f}(s)$, is defined by

$$\hat{f}(s) := \int_0^\infty t^{s-1}f(t) \, dt.$$ 

If $f \in L^p$ for all $p \in (1, \infty)$, then the above integral converges absolutely and uniformly on compacts subsets of the strip $0 < \Re s < 1$, so $\hat{f}(s)$ is an analytic function therein.

The Müntz operator\(^1\) $P$ is the linear operator defined formally on functions $f : [0, \infty) \to \mathbb{C}$ by

$$Pf(x) := \sum_{n=1}^\infty f(nx) - \frac{1}{x} \int_0^\infty f(t) \, dt.$$ 

It is clear that $K_\lambda P = PK_\lambda$ for all $\lambda > 0$, i.e., $P$ is an invariant operator as defined in the author’s paper [1]. In section 2 we study some basic properties of $P$.

### 1.2. A generalized strong Nyman–Beurling theorem

We recall that the strong Nyman Beurling criterion proved in [4] is the following theorem which both simplified and strengthened the result in ([10], [6]):

**Theorem 1.1.** $\text{RH} \iff \chi \in B(\rho_1)^{L^2}$. 

One obvious attempt to prove RH along these lines would be to tackle the Hilbert geometry problem of finding the distance from $\chi$ to the linear span of $\{K_\alpha \rho_1 : 1 \leq \alpha \leq n\}$, and then to let $n \to \infty$. However, the scalar products $\int_0^\infty \rho(1/at)\rho(1/bt) \, dt$, given by Vasyunin’s formulæ (see [13], [2]) have proved so far too complicated to compute the gramian determinants involved. Nevertheless a generalization of Vasyunin’s formula and a description in some depth of the autocorrelation function $t \mapsto \int_0^\infty \rho(1/t)\rho(1/xt) \, dt$ is found in [5].

Since it is verified trivially that

$$P\chi = -\rho_1,$$

Theorem 1.1 can be rephrased as

$$\text{RH} \iff \chi \in B(P\chi)^{L^2}.$$ 

We were thus led naturally to search for strong kernels $f \in L^2$ having the property that $Pf \in L^2$, and such that the analogous equivalence implication holds true:

$$\text{RH} \iff f \in B(\overline{PF})^{L^2}.$$ 

It is quite simple to see from a slight adaptation of the proof of Theorem 1.1 that step functions with non-vanishing Mellin transform in the critical strip are strong kernels. We doubt at present, that this can be of any use. Furthermore, if $f$ is a strong kernel, then both $cf$ for all $c \neq 0$, and $K_\lambda f$ for any $\lambda > 0$ are also strong kernels. But we do not know whether $f_1$ and $f_2$ being strong kernels implies that $f_1 + f_2$ is a strong kernel, even if $\hat{f}_1(s) + \hat{f}_2(s) \neq 0$ in the critical strip. That is,

\(^{1}\)Müntz [9] himself calls $xPF(x)$ the Euler difference (i.e., the difference between an integral in $(0, \infty)$ and its extended Riemann sums), whereas recently J.F. Burnol ([7], [8]) calls it the (Müntz-)modified Poisson summation of $f$. 

the class of strong kernels is a vertexless cone in $L_2$, but it is not known whether it is a subspace (exclusion made of the point 0). We rather turn our attention to a subspace of $L_2$ made up of differentiable kernels that might have interesting analytic properties, amongst them, but not exclusively, the possibility of simplifying the scalar products $\int_0^\infty Pf(ax)\bar{Pf}(bx)\,dx$.

**Definition 1.1.** The class of **good kernels** $\mathcal{G}$ is the family of functions $f \in C^1_0 \cap L_1$ with $\int_0^\infty t|f'(t)|\,dt < \infty$.

A simple important property of good kernels is the following:

**Lemma 1.1.** If $f \in \mathcal{G}$, then $f(t) = o(1/t)$ at infinity, and $f \in L_p(0, \infty)$, $(1 \leq p \leq \infty)$.

**Proof.** For any finite $T > 0$

$$\int_0^T tf'(t)\,dt = Tf(T) - \int_0^T f(t)\,dt,$$

which shows that there exists $\lim_{T \to \infty} Tf(T) = c$. If $c \neq 0$, then we would obtain that $f \notin L_1$. The $L_p$ statement is now obvious. \[\square\]

**Remark 1.1.** Not only are all good kernels $f \in L_p$ for $1 \leq p \leq \infty$, it will transpire below from Proposition 2.2 that $Pf \in L_p$ for $1 < p \leq \infty$. Furthermore it can be shown that $Pf \in C_0$.

Now we give a preliminary answer to our quest for non-trivial strong kernels. For any analytic function in the critical strip we shall denote

$$Z(g) := \{s : g(s) = 0, \quad 1/2 < \text{Re } s < 1\}.$$

**Theorem 1.2 (General Strong Theorem).** The following implications are true. Necessary condition for RH:

(1.2) \quad RH \implies \left( f \in \mathcal{G} \implies f \in \overline{B(Pf)}^{L_2} \right),

Sufficiency condition for RH:

(1.3) \quad \left( f \in \mathcal{G} \cap C_{00} \& f \in \overline{B(Pf)}^{L_2} \right) \implies (Z(\zeta) \subset Z(\hat{f})).

The obvious corollary is

**Theorem 1.3.** If $f \in \mathcal{G} \cap C_{00}$ and $Z(\hat{f}) = \emptyset$, then

$$RH \iff f \in \overline{B(Pf)}^{L_2}.$$

It is quite clear that we should like to remove the compact support condition in the sufficiency statement, but that has proved difficult to this moment.

In Section 2 we shall first establish some needed properties of the Müntz operator, then we prove the general strong Theorem 1.2 in Section 3.
2. Some properties of the Müntz operator

2.1. Existence of \( Pf \). We first recall that the Müntz operator is well defined for a space of functions containing \( L_1 \). This follows immediately from J. F. Burnol’s work (Lemma 2.1 in [7]). The neat proof of his lemma is worth repeating in detail.

**Lemma 2.1 (J. F. Burnol).** If \( f \in L_1(\epsilon, \infty) \) for some \( \epsilon > 0 \), then

\[
\int_{\epsilon}^{\infty} \sum_{n=1}^{\infty} |f(nx)| \frac{dx}{x} < \infty.
\]

An obvious consequence is

**Corollary 2.1.** \( Pf(x) \) is well defined a.e. for all \( f \in \mathcal{G} \), and it is locally integrable.

**Proof of Lemma 2.1.** Fix any \( \epsilon > 0 \). Now use the monotone convergence twice in the following chain, first to take the sum out, then to put it back in:

\[
\int_{\epsilon}^{\infty} \sum_{n=1}^{\infty} |f(nx)| \frac{dx}{x} = \sum_{n=1}^{\infty} \int_{\epsilon}^{\infty} |f(nx)| \frac{dx}{x} = \sum_{n=1}^{\infty} \int_{0}^{\infty} \chi \left( \frac{\epsilon}{x} \right) |f(nx)| \frac{dx}{x} = \sum_{n=1}^{\infty} \int_{0}^{\infty} \chi \left( \frac{n\epsilon}{x} \right) |f(x)| \frac{dx}{x} = \int_{0}^{\infty} \sum_{n=1}^{\infty} \chi \left( \frac{n\epsilon}{x} \right) |f(x)| \frac{dx}{x} \leq \frac{1}{\epsilon} \int_{\epsilon}^{\infty} |f(x)| dx.
\]

\[ \square \]

2.2. A convolution operator. Let \( f : [0, \infty) \to \mathbb{C} \) be measurable. For every \( \sigma \in \mathbb{R} \) introduce the norm

\[ \nu_\sigma(F) = \int_{0}^{\infty} t^\sigma |F(t)| \, dt, \]

which is indeed the norm of the Banach space \( L_1((0, \infty), t^\sigma dt) \). We now define, formally at first, the operator \( T_F \) by

\[
T_F G(x) := \int_{0}^{\infty} G(x t^{-1}) F(t) \, dt.
\]

(2.1)

Note that \( T_F \) is invariant, i.e., it commutes with all dilations \( K_\lambda \).
Proposition 2.1. If $\nu_{1/p}(F) < \infty$ for some fixed $p \in [1, \infty]$, then the linear operator $T_F$ acts continuously from $L_p$ to $L_p$, with norm satisfying

$$\|T_F\|_{L_p} \leq \nu_{1/p}(F).$$

Remark 2.1. A simple example of this operator is the following: for any $f \in G$ we have

$$f = -T_f' \chi.$$  
Here $\nu_1(f') < \infty$ and $\chi$ is in all $L_p$. This seemingly trivial identity plays a crucial role in the proof of the necessity criterion.

Proof. If $p = \infty$ the result is trivial. For $1 \leq p < \infty$ let $G \in L_p$. Now we write the integral in (2.1) as a true convolution in the locally compact, multiplicative, abelian group $A = (0, \infty)^\times$ provided with Haar measure $t^{-1} dt$:

$$x^{1/p} T_F G(x) = \int_0^\infty (xt^{-1})^{1/p} G(xt^{-1}) t^{1+1/p} F(t) \frac{dt}{t} = (\phi \ast \psi)(x),$$
where $\phi(t) := t^{1/p} G(t)$, $\psi(t) := t^{1+1/p} F(t)$, and $\phi \in L_p(A)$, $\psi \in L_1(A)$. Hence Young’s inequality $\|\phi \ast \psi\|_{L_p(A)} \leq \|\phi\|_{L_p(A)} \|\psi\|_{L_1(A)}$ becomes

$$\|T_F G\|_p \leq \nu_{1/p}(F)\|G\|_p.$$ 

2.3. $P$ as a convolution operator. For some purposes the following representation is an alternative definition of the Müntz operator $P$.

Proposition 2.2. Let $f \in G$; then

$$Pf(x) = T_f \rho_1(x) = \int_0^\infty \rho_1(xt^{-1}) f'(t) \, dt,$$
with

$$\|Pf\|_p \leq \nu_{1/p}(f')\|\rho_1\|_p, \quad 1 < p < \infty.$$ 
A fortiori $Pf \in L_p$ for $1 < p \leq \infty$.

Remark 2.2. Several comments are in order about this representation for $Pf$: naturally the equation (2.4) is to be interpreted in the a.e. sense. It is easy to see furthermore that $P$ is not continuous relative to any $L_p(0, \infty)$-norm due to the troublesome presence of the derivative $f'$ in the convolution (2.4). On the other hand it is gratifying to see that for $f \in G$ both $f, Pf \in L_p$ for $1 < p \leq \infty$, very much so for $p = 2$. The index $p = 1$ fails because $\rho_1 \notin L_1$.

It is noteworthy too that one can prove that the representing integral for $Pf$ is a continuous function vanishing at infinity, whose value at the origin is $-\frac{1}{2} f(0)$, but, as that is of no use presently, we defer it to a future note.

We can now prove the main proposition of this Section:
Proof of Proposition 2.2. In view of (1.1) we have for each finite \( T > 0 \)

\[
\int_0^T \rho \left( \frac{t}{x} \right) f'(t) \, dt = \int_0^T \left( \frac{t}{x} - \sum_{n=1}^{\infty} \chi \left( \frac{nx}{t} \right) \right) f'(t) \, dt
\]

(2.5)

\[
= \frac{1}{x} \int_0^T t f'(t) \, dt - \int_0^T \sum_{n=1}^{\infty} \chi \left( \frac{nx}{t} \right) f'(t) \, dt,
\]

where integrating by parts we get

(2.6)

\[
\int_0^T t f'(t) \, dt \to \int_0^\infty f(t) \, dt, \quad T \to \infty
\]

since \( Tf(T) \to 0 \) (see Lemma 1.1). On the other hand the monotone convergence theorem yields

\[
\int_0^T \sum_{n=1}^{\infty} \chi \left( \frac{nx}{t} \right) f'(t) \, dt = \sum_{n=1}^{\infty} \int_0^T \chi \left( \frac{nx}{t} \right) f'(t) \, dt
\]

\[
= \sum_{n \leq T/x} \int_{nx}^T f'(t) \, dt
\]

\[
= \left[ f(T) - \sum_{n \leq T/x} f(nx) \right].
\]

Then using Burnol’s Lemma 2.1 we see that the above sum converges absolutely a.e. as \( T \to \infty \), and, since \( Tf(T) \to 0 \), we get

(2.7)

\[
\int_0^T \sum_{n=1}^{\infty} \chi \left( \frac{nx}{t} \right) f'(t) \, dt \to \sum_{n=1}^{\infty} f(nx), \quad (T \to \infty).
\]

Therefore inserting (2.6) and (2.7) into (2.5) we obtain the desired representation (2.4) for \( Pf(x) \).

Finally the norm inequality follows immediately from inequality (2.3) of Proposition 2.1. \(
\square
\)

2.4. Müntz’s formula. It has been shown by Müntz [9] that for all \( f \in C^1 \)
with \( f(x) \), and \( xf'(x) \) of order \( x^{-\alpha} \) at infinity for some \( \alpha > 1 \), one has

(2.8)

\[
\zeta(s) \hat{f}(s) = (Pf)^\wedge(s), \quad (0 < \Re s < 1).
\]

It is interesting to remark that for the special non-smooth kernel \( f = \chi \), where we recall that \( \rho_1 = -P\chi \), the formula is also valid, in fact it is the proto-Müntz formula, namely

(2.9)

\[
\frac{\zeta(s)}{-s} = \int_0^\infty x^{s-1} \rho_1(x) \, dx, \quad 0 < \Re s < 1,
\]

which is the basis both, for Müntz’s original proof of (2.8), as well as for the Nyman–Beurling theorem, and our earlier strengthened Theorem 1.1 Müntz showed in [9].
that numerous, if not most proofs of the functional equation for the Riemann zeta-
function are derived from (2.8). This is fully discussed in chapter 2 of Titchmarsh’s
monograph [11], [12], in particular Section 2.11 contains a different proof of Müntz’s
formula.

We now present a somewhat more general version of Müntz formula for smooth
\( f \). Not the more general version, of course, but certainly sufficient for our immediate
purposes. There seems to be no absolutely most general formulation; however,
J. F. Burnol has gone into this matter in great depth in [8].

**Theorem 2.1 (Müntz’s formula).** If \( f \in \mathcal{G} \), then Müntz’s formula (2.8) holds
true.

**Proof.** Since \( f \) and \( Pf \) are in \( L_p \) for \( 1 < p < \infty \) (see Remark 2.2), then the
Mellin transforms in Müntz’s formula (2.8) are well defined, absolutely convergent
integrals in the strip \( 0 < \Re s < 1 \). Do note also that \( \int_0^\infty t^\sigma |f'(t)| \, dt < \infty \) for
\( 0 \leq \sigma \leq 1 \). On the right-hand side of (2.8) we substitute \( Pf \) by its pseudo-
convolution representation in (2.4) and employ Fubini’s theorem together with (2.9)
to obtain

\[
\int_0^\infty x^{s-1} Pf(x) \, dx = \int_0^\infty x^{s-1} \int_0^\infty \rho \left( \frac{t}{x} \right) f'(t) \, dt \, dx
\]

\[
= \int_0^\infty \int_0^\infty x^{s-1} \rho \left( \frac{t}{x} \right) dx \, f'(t) \, dt
\]

\[
= \int_0^\infty \int_0^\infty (ut)^{s-1} \rho \left( \frac{1}{u} \right) du \, t \, f'(t) \, dt
\]

\[
= \int_0^\infty u^{s-1} \rho \left( \frac{1}{u} \right) du \int_0^\infty t^s \, f'(t) \, dt
\]

\[
= \zeta(s) \int_0^\infty t^s \, f'(t) \, dt = \zeta(s) \int_0^\infty t^{s-1} f(t) \, dt,
\]

where the last integration by parts above uses the fact that \( tf(t) \to 0 \) as \( t \to \infty \)
(Lemma 1.1).

It remains to justify the interchange of integrations involved in the second
equality of the above chain. To do this follow the same steps with the appropriate
absolute values; indeed, let \( \sigma = \Re s \), \( 0 < \sigma < 1 \); then

\[
\int_0^\infty \int_0^\infty x^{\sigma-1} \rho \left( \frac{t}{x} \right) |f'(t)| \, dt \, dx = \int_0^\infty \int_0^\infty x^{\sigma-1} \rho \left( \frac{t}{x} \right) dx \, |f'(t)| \, dt
\]

\[
= \int_0^\infty \int_0^\infty (ut)^{\sigma-1} \rho \left( \frac{1}{u} \right) du \, t \, |f'(t)| \, dt
\]

\[
= \frac{\zeta(\sigma)}{-\sigma} \int_0^\infty t^\sigma |f'(t)| \, dt < \infty.
\]

This concludes the proof. \( \square \)

\(^2\)We have discussed formally an even more general recipe that produces a potentially infinite
number of such proofs in [3].
3. The proof of the main Theorem 1.2

3.1. The necessity criterion. No doubt it can qualify as daydreaming, but the necessity part of the theorem would seem like a good test to disprove RH if one holds on to the hope of finding an analytic kernel with simple scalar products. It is also worth remarking how simple the proof turns out to be in relation to the original Nyman–Beurling theorem, and even to that of the strengthened version. It is quite puzzling to note that no condition whatsoever is required of the Mellin transform of the kernel, which is quite surprising, as the Mellin transform $\hat{\chi}(s) = \frac{1}{s}$ plays a very important role in the proof of the necessity condition in our strong Nyman–Beurling Theorem 1.1. This bears reflecting on.

**Proof of the necessity criterion (1.2).** Assume RH is true and let $f$ be a good kernel. By the strengthened Nyman–Beurling Theorem 1.1 there is a sequence $\{h_n : n \in \mathbb{N}\} \subset B(\rho_1)$ such that

$$\|h_n + \chi\|_2 \to 0, \quad (n \to \infty).$$

There is no loss of generality in writing

$$h_n = \sum_{a=1}^{n} c_{n,a} K_a \rho_1.$$

Now we define $H_n := T_f h_n$. Note that the invariance of $T_f$ and the important representation $Pf = T_f \rho_1$ given by Proposition 2.2 yield

$$H_n = \sum_{a=1}^{n} c_{n,a} K_a Pf,$$

so that $H_n \in B(Pf)$. But $-f = T_f \chi$ as noted before in equation (2.2), hence

$$\|H_n - f\|_2 = \|T_f (h_n + \chi)\|_2 \to 0, \quad (n \to \infty),$$

since $T_f$ is a bounded operator from $L_2$ to itself as was shown in Proposition 2.1. This yields $f \in B(Pf)^{L_2}$. □

3.2. The sufficiency criterion. We now prove the sufficiency criterion in Theorem 1.2. One should certainly like to remove the condition that the good kernel be of compact support. This would allow the consideration of analytic kernels which may indeed prove to yield more tractable scalar products.

**Remark 3.1.** One obviously expects a generalization to a sufficiency criterion for the non-vanishing of $\zeta(s)$ in the half-plane $\text{Re} \, s > 1/p$ in terms of $L_p$ approximations. But we shall not bother with it at present, particularly since we have neither worked out the necessity criterion in the $L_p$-case, nor have done this yet for the strengthened Nyman–Beurling Theorem 1.1.

**Proof of the sufficiency criterion (1.3).** Let $f \in \mathcal{G} \cap C_{00}$, and assume $f \in B(Pf)^{L_2}$. Let $\zeta(s) = 0$ for some fixed $s$ with $\sigma = \text{Re} \, s \in (\frac{1}{2}, 1)$. Our aim is to prove that $\hat{f}(s) = 0$. By hypothesis there is a sequence $h_n \in B(Pf)$ such that $\|h_n - f\|_2 \to 0$. Now apply the invariant operator $V = I - 2K_2$ as follows.
Define $F := Vf$, and $H_n := Vh_n$. By invariance of $V$, each $H_n \in B(PF)$. Clearly $F \in G \cap C_0$, and $\int_0^\infty F(x)dx = 0$. These two facts together imply that there is an $A > 0$ such $PF(x) = 0$ for $x > A$, and thus every $H_n(x) = 0$ also vanishes for $A > 0$. Further, by $L_2$-continuity of $V$, $\|H_n - F\|_2 \to 0$. But Müntz’s formula (2.8) implies $H_n(s) = 0$, and therefore

$$-\hat{F}(s) = \int_0^A x^{s-1}(H_n(x) - F(x))dx.$$

But these integrals tend to zero by Schwarz’s inequality since $x^{s-1}$ is square integrable in $(0, A)$. Hence $0 = \hat{F}(s) = (1 - 2^{1-s})\hat{f}(s)$, so $\hat{f}(s) = 0$. □
