Abstract. We show that for Wintgen ideal submanifolds in real space forms the (intrinsic) Ricci principal directions and the (extrinsic) Casorati principal directions coincide.

1. Wintgen Ideal Submanifolds of Real Space Forms

Let $M^n$ be an $n$-dimensional Riemannian submanifold of an $(n + m)$-dimensional real space form $\tilde{M}^{n+m}(c)$ of constant sectional curvature $c$ and let $g, \nabla$ and $\tilde{g}, \tilde{\nabla}$ be the Riemannian metric and the corresponding Levi–Civita connection on $M^n$ and on $\tilde{M}^{n+m}(c)$, respectively. Tangent vector fields on $M^n$ will be written as $X, Y, \ldots$ and normal vector fields on $M^n$ in $\tilde{M}^{n+m}(c)$ will be written as $\xi, \eta, \ldots$. The formulae of Gauss and Weingarten, concerning the decomposition of the vector fields $\tilde{\nabla}_X Y$ and $\tilde{\nabla}_X \xi$, respectively, into their tangential and normal components along $M^n$ in $\tilde{M}^{n+m}(c)$ are given by $\tilde{\nabla}_X Y = \nabla_X Y + h(X,Y) \xi$ and $\tilde{\nabla}_X \xi = -A_\xi(X) + \nabla^\perp_X \xi$, respectively, whereby $h$ is the second fundamental form and $A_\xi$ is the shape operator or Weingarten map of $M^n$ with respect to the normal vector field $\xi$, such that $\tilde{g}(h(X,Y), \xi) = g(A_\xi(X), Y)$, and $\nabla^\perp$ is the connection in the normal bundle.

The mean curvature vector field $\tilde{H}$ is defined by $\tilde{H} = \frac{1}{n}tr h$ and its length $\|\tilde{H}\| = H$ is the extrinsic mean curvature of $M^n$ in $\tilde{M}^{n+m}(c)$. A submanifold $M^n$ in $\tilde{M}^{n+m}(c)$ is totally geodesic when $h = 0$, totally umbilical when $h = g\tilde{H}$, minimal when $H = 0$ and pseudo–umbilical when $\tilde{H}$ is an umbilical normal direction.

Let $\{E_i, \ldots, E_n, \xi_1, \ldots, \xi_m\}$ be any adapted orthonormal local frame field on the submanifold $M^n$ in $\tilde{M}^{n+m}(c)$, denoted for short also as $\{E_i, \xi_a\}$, whereby $i, j, \ldots \in \{1, 2, \ldots, n\}$ and $a, \beta, \ldots \in \{1, 2, \ldots, m\}$.

By the equation of Gauss, the $(0,4)$ Riemann–Christoffel curvature tensor of a submanifold $M^n$ in $\tilde{M}^{n+m}(c)$ is given by $R(X, Y, Z, W) = \tilde{g}(h(Y, Z), h(W, X)) - \tilde{g}(h(X, Z), h(Y, W)) + \tilde{c}[\tilde{g}(Y, Z)g(W, X) - g(X, Z)g(Y, W)]$.

The $(0,2)$ Ricci curvature tensor of $M^n$ is defined by $S(X, Y) = \sum_i R(X, E_i, E_i, Y)$ and the metrically corresponding $(1,1)$ tensor or Ricci operator will also be denoted by $S$: $g(S(X), Y) = S(X, Y)$. Since $S$ is symmetric
there exists on $M^n$ an orthonormal set of eigenvector fields $R_1, \ldots, R_n$ which determine the intrinsic, Ricci principal directions of the Riemannian manifold $M^n$, and the corresponding eigenfunctions $\text{Ric}_1, \ldots, \text{Ric}_n$ are the Ricci curvatures of $M^n$: $\text{S}(R_i) = \text{Ric}_i R_i$. A Riemannian manifold $M^n$ is an Einstein space when $S = \text{Ric}$, or still when all Ricci curvatures are equal $\text{Ric}_1 = \cdots = \text{Ric}_n = \text{Ric}$, $M^n$ is a quasi–Einstein space when it has a Ricci curvature of multiplicity $\geq n - 1$ and $M^n$ is a 2-quasi–Einstein space when it has a Ricci curvature of multiplicity $\geq n - 2$. The scalar curvature of a Riemannian manifold $M^n$ is defined by $\tau = \sum_{i,j} K(E_i \wedge E_j)$ whereby $K(E_i \wedge E_j) = R(E_i, E_j, E_j, E_i)$ is the sectional curvature for the plane section $\pi = E_i \wedge E_j$, $i \neq j$, and the normalized scalar curvature function $\tau$ of $M^n$ is defined by $\rho = (2/n(n-1))\tau$. By the equation of Ricci, the normal curvature tensor of a submanifold $M^n$ in $M^{n+m}(c)$ is given by $R^i(X,Y,Z) = g[[A_1, A_2](X), Y]$, whereby $[A_1, A_2] = A_1 A_2 - A_2 A_1$, which, as already observed by Cartan [1], implies that the normal connection is flat or trivial if and only if all shape operators $A_1$ are simultaneously diagonalisable. The normal scalar curvature of a submanifold $M^n$ is defined by $\tau^i = \left(\sum_{\alpha<\beta} R^i(E_\alpha, E_\beta, E_\beta, E_\alpha)\right)^{1/2}$ and the normalized normal scalar curvature of $M^n$ is defined by $\rho^i = (2/n(n-1))\tau^i$.

For surfaces $M^2$ in $E^3$, the Euler inequality $K \leq H^2$, whereby $K$ is the intrinsic Gauss curvature of $M^2$ at once follows from the fact that that $K = k_1 k_2$ and $H = \frac{1}{2}(k_1 + k_2)$, whereby $k_1$ and $k_2$ are the principal curvatures of $M^2$ in $E^3$, and $K = H^2$ if and only if $M^2$ is totally umbilical, i.e. if $k_1 = k_2$, or still, by a Theorem of Meusnier, if $M^2$ is (part of) a plane $E^2$ or of a round sphere $S^2$ in $E^3$. For surfaces $M^2$ in $E^4$, in 1979 Wintgen [21] proved that the Gauss curvature $K = \tau$ and the squared mean curvature $H^2$ and the extrinsic normal scalar curvature $K^i = \tau^i$ always satisfy the inequality $K \leq H^2 - K^i$, and that in this weak inequality actually the equality holds, $K = H^2 - K^i$, if and only if the curvature ellipses $E = \{h(U, U) \mid U \in TM$ and $||U|| = 1\}$ in the normal planes of $M^2$ in $E^3$ are circles. These results of Wintgen were extended to all surfaces $M^2$ in $E^{3+m}$, regardless their co-dimensions $m$ by Rouchel [19] and Guadalupe, Rodriguez [12]. In 1999, De Smet, Dillen, Vrancken, one of the authors [7] proved the generalized Wintgen inequality

$$\rho \leq H^2 - \rho^i + c,$$  

for all $n$-dimensional submanifolds $M^n$ with co-dimension $m = 2$ in real space forms $\tilde{M}^{n+2}(c)$, gave a characterization of the equality situation in terms of an explicit description of the second fundamental form and conjectured (*) to hold for all $n$-dimensional submanifolds $M^n$ with arbitrary co-dimensions $m$ in real space forms $\tilde{M}^{n+m}(c)$. Recently, Choi and Lu [6], Lu [16] and Ge–Tang [11] proved that indeed (*) holds in full generality for all submanifolds $M^n$ in $\tilde{M}^{n+m}(c)$ and gave a characterization of the equality situation in terms of an explicit description of the second fundamental form, thus establishing the following.

**Theorem A.** Let $M^n$ be a submanifold in a real space form $\tilde{M}^{n+m}$. Then the soft inequality (*) holds and in (*) actually the equality holds if and only if, with respect to a suitable adapted orthonormal frame $\{E_i, \xi_a\}$ on $M^n$ in $\tilde{M}^{n+m}$, the shape operators of the submanifold take the following forms:

$$A_1 = \begin{bmatrix} \lambda_1 & \mu & 0 & \cdots & 0 \\ \mu & \lambda_1 & 0 & \cdots & 0 \\ 0 & 0 & \lambda_1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & \lambda_1 \end{bmatrix},$$

$$A_2 = \begin{bmatrix} \lambda_2 + \mu & 0 & 0 & \cdots & 0 \\ 0 & \lambda_2 - \mu & 0 & \cdots & 0 \\ 0 & 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & \lambda_2 \end{bmatrix},$$

where $\lambda_1, \lambda_2$ are the eigenvalues of the intrinsic, Ricci principal curvatures and $\mu$ the extrinsic curvature.
value of the intrinsic normalised scalar curvature

whereby \( \lambda_1, \lambda_2, \lambda_3 \) and \( \mu \) are real functions on \( M^n \).

The submanifolds \( M^n \) in \( \tilde{M}^{n+m}(c) \) for which

\[
\rho = H^2 - \rho^1 + c \quad (**)
\]

are called Wintgen ideal submanifolds; for many examples and for geometrical properties of such submanifolds, see e.g. [3, 6, 7, 9–12, 14, 16, 18, 19]. A motivation for this terminology might go as follows: for all possible isometric immersions of a Riemannian manifold \( M^n \) into a real space form \( \tilde{M}^{n+m}(c) \), by (*) the value of the intrinsic normalised scalar curvature \( \rho \) of \( M^n \) puts a lower bound to the possible values of the extrinsic “stress” \( H^2 - \rho^1 + c \) that \( M^n \) in any case cannot avoid “to undergo” as a submanifold in an ambient space \( \tilde{M}^{n+m}(c) \), and, from this point of view, every Wintgen ideal submanifold \( M^n \) actually realises a particular shape in \( \tilde{M}^{n+m}(c) \) such that this extrinsic stress does everywhere assume its theoretically smallest possible value as given by \( \rho \). A frame \( \{E_1, \ldots, E_n, \xi_1, \ldots, \xi_m\} \) with the corresponding shape operators \( A_i \), as stated in Theorem A is called a Choi–Lu frame on \( M^n \) in \( \tilde{M}^{n+m}(c) \) and its distinguished tangent plane \( E_1 \wedge E_2 \) is called the Choi–Lu plane of the Wintgen ideal submanifolds concerned [9, 10].

2. The Casorati Principal Directions of Submanifolds

For any submanifold \( M^n \) in some ambient Riemannian manifold \( \tilde{M}^{n+m} \), the \((1,1)\) tensor field \( A^C = \sum A_i^2 \) is called its Casorati operator and the Casorati curvature (as such) of \( M^n \) in \( \tilde{M}^{n+m} \) is defined by \( \bar{C} = \frac{1}{n} \text{tr} A^C = \frac{1}{n} ||h||^2 \). The Casorati operator being symmetric there exists on \( M^n \) an orthonormal set of eigenvector fields \( F_1, \ldots, F_n \), which determine the extrinsic, Casorati principal directions of the submanifold \( M^n \) in \( \tilde{M}^{n+m} \), and the corresponding eigenfunctions \( c_1, \ldots, c_n \), (all \( \geq 0 \)), are its extrinsic principal curvatures or the Casorati principal curvatures of \( M^n \) in \( \tilde{M}^{n+m} \); \( A^C(F_i) = c_i F_i \). For the geometrical meanings of these notions, which essentially go back to Jordan and Casorati, see [2, 8, 13, 15, 20].

A hypersurface \( M^n \) in a Riemannian space \( \tilde{M}^{n+1} \) is called umbilical when its shape operator is proportional to the identity, i.e. has an eigenvalue of multiplicity \( n \), or still, when all its principal curvatures are equal. A hypersurface \( M^n \) in \( \tilde{M}^{n+1} \) is called quasi–umbilical when its shape operator has an eigenvalue of multiplicity \( \geq n - 1 \), (see e.g. [4]), and is called 2–quasi–umbilical when its shape operator has an eigenvalue of multiplicity \( \geq n - 2 \), ([5], [17]). Similarly, a general submanifold \( M^n \) in some ambient Riemannian manifold \( \tilde{M}^{n+m} \) is called Casorati umbilical when its Casorati operator is proportional to the identity, i.e. has an eigenvalue of multiplicity \( n \), or still, when all its Casorati principal curvatures are equal. A submanifold \( M^n \) in \( \tilde{M}^{n+m} \) is called Casorati quasi–umbilical when its Casorati operator has an eigenvalue of multiplicity \( \geq n - 1 \), and is called Casorati 2–quasi–umbilical when its Casorati operator has an eigenvalue of multiplicity \( \geq n - 2 \).

From Theorem A it follows that the Casorati operator of the Wintgen ideal submanifolds \( M^n \) in real space forms \( \tilde{M}^{n+m}(c) \) is given by

\[
A^C = \begin{bmatrix}
L + 2\lambda_2\mu + 2\mu^2 & 2\lambda_1\mu & 0 & \cdots & 0 \\
2\lambda_1\mu & L + 2\mu^2 - 2\lambda_2\mu & 0 & \cdots & 0 \\
0 & 0 & L & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & L \\
\end{bmatrix},
\]

whereby \( L = \lambda_1^2 + \lambda_2^2 + \lambda_3^2 \). Its eigenvalues are \( c_1 = L + 2\mu^2 + 2\mu(\lambda_1^2 + \lambda_2^2)^{1/2} \), \( c_2 = L + 2\mu^2 - 2\mu(\lambda_1^2 + \lambda_2^2)^{1/2} \), \( c_3 = \cdots = c_n = L \), and, in terms of the basic vector fields \( E_1 \) and \( E_2 \) of the Choi–Lu frame along \( M^n \) in \( \tilde{M}^{n+m}(c) \), the
vector fields $\tilde{F}_1 = \{\lambda_2 + (\lambda_1^2 + \lambda_2^2)^{1/2}\}E_1 + \lambda_1 E_2$ and $\tilde{F}_2 = \{\lambda_2 - (\lambda_1^2 + \lambda_2^2)^{1/2}\}E_1 + \lambda_1 E_2$ determine the $1$–dimensional eigenspaces of $A^c$ corresponding to $c_1$ and $c_2$, respectively, unless when $\lambda_1 = \lambda_2 = 0$ and $\mu \neq 0$, in which case the Choi–Lu plane itself is a $2$–dimensional eigenspace of $A^c$, or when $\mu = 0$, in which case of course the Casorati principal directions are undetermined, $A^C$ then being proportional to the identity operator, (and, even stronger, $M^n$ then being totally umbilical); and, in any case, the tangent subspace $E_3 \wedge \cdots \wedge E_n$ of $M^n$ is an $(n-2)$–dimensional eigenspace of $A^C$ corresponding to the Casorati curvature $L$. Hence, in particular we have the following.

**Theorem 2.1.** Every Wintgen ideal submanifold $M^n$ in a real space form $\tilde{M}^{m+n}(c)$ is Casorati $2$–quasi–umbilical. When $M^n$ is not totally umbilical, then the orthogonal complement of its Choi–Lu plane is its $(n-2)$–dimensional Casorati eigenspace.

3. **The Ricci Principal Directions of Riemannian Manifolds**

From Theorem A, via the Gauss equation, it follows that the Ricci operator of the Wintgen ideal submanifolds $M^n$ in real space forms $\tilde{M}^{m+n}(c)$ is given by

$$S = \begin{pmatrix}
(n-1)c + (n-2)\mu\lambda_2 - 2\mu^2 & (n-2)\mu\lambda_1 & 0 & \cdots & 0 \\
(n-2)\mu\lambda_1 & (n-1)c - (n-2)\mu\lambda_2 - 2\mu^2 & 0 & \cdots & 0 \\
0 & 0 & (n-1)c & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & (n-1)c
\end{pmatrix},$$

whereby $c = L+c$. Its eigenvalues are $\text{Ric}_1 = (n-1)c - 2\mu^2 + (n-2)\mu(\lambda_1^2 + \lambda_2^2)^{1/2}$, $\text{Ric}_2 = (n-1)c - 2\mu^2 - (n-2)\mu(\lambda_1^2 + \lambda_2^2)^{1/2}$, $\text{Ric}_3 = \cdots = \text{Ric}_n = (n-1)c$, and, in terms of $E_1$ and $E_2$ the vector fields $\tilde{R}_1 = \{\lambda_2 + (\lambda_1^2 + \lambda_2^2)^{1/2}\}E_1 + \lambda_1 E_2$ and $\tilde{R}_2 = \{\lambda_2 - (\lambda_1^2 + \lambda_2^2)^{1/2}\}E_1 + \lambda_1 E_2$ determine the $1$–dimensional eigenspaces of $S$ corresponding to $\text{Ric}_1$ and $\text{Ric}_2$, respectively, unless when $\lambda_1 = \lambda_2 = 0$ and $\mu \neq 0$, in which case the Choi–Lu plane itself is a $2$–dimensional eigenspace of $S$, or when $\mu = 0$, in which case of course the Ricci principal directions are undetermined, $M^n$ then being an Einstein space, (and, even stronger, $M^n$ then being totally umbilical, and thus being a real space form itself); and, in any case, the tangent subspace $E_3 \wedge \cdots \wedge E_n$ of $M^n$ is an $(n-2)$–dimensional eigenspace of $S$ corresponding to the Ricci curvature $(n-1)c$. Hence, in particular, we have the following.

**Theorem 3.1.** Every Wintgen ideal submanifold $M^n$ in a real space form $\tilde{M}^{m+n}(c)$ is Ricci $2$–quasi–umbilical. When $M^n$ is not totally umbilical, then the orthogonal complement of its Choi–Lu plane is its $(n-2)$–dimensional Ricci eigenspace.

4. **Main Result**

From the extrinsic geometric point of view, the Casorati principal directions of a submanifold $M^n$ in a Riemannian space $\tilde{M}^{m+n}$ likely are its most important tangent directions while, from the intrinsic geometric point of view, for a Riemannian manifold $M^n$ likely its most important tangent directions are its Ricci principal directions. And, from the formulae given in Sections 2 and 3, clearly following

**Theorem 4.1.** On every Wintgen ideal submanifold in a real space form the Casorati and the Ricci principal directions do coincide,

we may conclude that the particular shape any Wintgen ideal submanifold $M^n$ does realise in ambient real space forms $\tilde{M}^{m+n}(c)$ in order to undergo the very least possible amount of extrinsic stress as allowed by its normalised intrinsic Riemannian scalar curvature, manifests the geometrical property that the principal tangent directions which are determined by this shape, namely its Casorati principal directions, are the same as the principal intrinsic tangent directions of its Riemannian structure, namely its Ricci principal directions.
