Abstract. The purpose of this article is to deal with the uniqueness problems of meromorphic functions partially sharing values. It is showed that two entire functions $f$ and $g$ with $P_2(f) < 1$ and periodic restriction must be identically if

$$E(0, f(z)) = E(0, g(z)) \text{ except for a possible set } G_1 \text{ and } E(1, f(z)) = E(1, g(z)) \text{ except for a possible set } G_2 \text{ with } N(r, G_i) = O(r^\lambda), (i = 1, 2), \text{ where } \lambda < 1 \text{ is a fixed constant.}$$

This result is a generalization of some previous works of Chen in [5] and Cai and Chen in [7].

1. Introduction and main results

The paper mainly concerns the uniqueness problem of the periodic meromorphic function partially sharing “1CM + 1IM” with another meromorphic function. This problem was originated from the well-known Nevanlinna five theorem in 1920s (see, e.g., [17]-[21]), which states that two non-constant meromorphic functions must be identically if they share five values IM. Here, we say two meromorphic functions $f$ and $g$ share a IM if $f - a$ and $g - a$ have the same zeros or $E(a, f) = E(a, g)$. And the notation $E(a, f)$ denotes the set of all the zeros of $f(z) - a$, where a zero is counted one time. In addition, we say $f$ and $g$ share a CM if $f - a$ and $g - a$ have the same zeros with multiplicities or $E(a, f) = E(a, g)$. And the notation $E(a, f)$ denotes the set of all the zeros of $f(z) - a$, where a zero with multiplicity $m$ is counted $m$ times. Later on, Nevanlinna gave the famous four values theorem. Since then, the uniqueness theory of meromorphic functions has become an extensive subfield of the value distribution theory. Many researchers focused their efforts on the aspect (see, e.g., [9, 10]). In 1989, in his Ph.D thesis, Brosch considered the uniqueness problem in another direction. He firstly studied the periodicity relationship of two meromorphic functions if they shared three values CM. In fact, Brosch derived that if a periodic meromorphic function $f$ shares three values CM with another meromorphic function $g$, then $g$ is also periodic. In Brosch’s work, the forms of $f$ and $g$ were not given. So, it becomes an interesting work to seek the forms of $f$ and $g$. The work has been done by Zheng in [23]. More precisely, Zheng derived the following result.

\textbf{Theorem A.} (see [23]) Let $f(z)$ and $g(z)$ be two non-constant meromorphic functions with the same period $c(\neq 0)$. Suppose that $\mu_2(f) < 1$. If $f(z)$ and $g(z)$ share 0, 1, $\infty$ CM, then $f(z) \equiv g(z)$ or $f(z)$ and $g(z)$ assume
the following form \( f(z) = \frac{e^{a_{1}z} - 1}{e^{a_{2}z} - 1}, \) \( g(z) = \frac{e^{b_{1}z} - 1}{e^{b_{2}z} - 1}, \) where \( a_{1} = \frac{2\pi i}{c}, a_{2} = \frac{2\pi i}{c}, b_{1}, b_{2} \) are constants, and \( m, k \) are integers.

Recently, the difference analogues to Nevanlinna’s theory was established by Halburd and Korhonen [14, 15], Chiang and Feng [8], independently, and improved by Halburd, Korhonen, and Tohge [16] from finite order of meromorphic functions to infinite order (hyper-order strictly less than 1). And it becomes a powerful theoretical tool to study the uniqueness problems of meromorphic functions taking into account their shifts (see, e.g., [3, 12, 13]) or difference operators (see, e.g., [18, 22]), and so on. Due to the difference analogues to Nevanlinna’s theory, Chen and his co-worker further discussed the above uniqueness problem in [4]. And the follow-up work was also due to Chen. In 2017, he derived the following theorem.

**Theorem B.** (see [5, Theorem 1.3]) Let \( f(z) \) and \( g(z) \) be two non-constant meromorphic functions with the same period \( c \neq 0 \). Suppose that \( \rho_{2}(f) < 1 \). If \( f(z) \) and \( g(z) \) share \( 0, \infty \) CM and \( 1 \) IM, then either (i) \( f(z) \equiv g(z) \); or (ii) \( f(z) = e^{\alpha z} g(z) \) and \( \mu(f) = \mu(g) = 1 \), where \( a = \frac{2\pi i}{c}, b \) are constants, and \( k \) is an integer.

It is pointed out that for entire functions, Chen in [6] weakened the shared values condition “\( 2CM + 1IM \)” to that of “\( 1CM + 2IM \)” in his PhD thesis. Later, Cai and Chen further improved Chen’s result by weakening the condition “\( 1CM + 2IM \)” to that of “\( 1CM + 1IM \)” as follows.

**Theorem C.** (see [7, Theorem 1.6]) Let \( f(z) \) and \( g(z) \) be two non-constant entire functions. Let \( c \in \mathbb{C}\{0\} \), and let \( a_{1}, a_{2} \) be two distinct finite complex numbers. Suppose that \( \mu(f) \neq 1, \rho_{2}(f) < 1, \) and \( f(z) = f(z + c) \) for all \( z \in \mathbb{C}. \) If \( f(z) \) and \( g(z) \) share \( a_{1} \) CM, \( a_{2} \) IM, then \( f(z) \equiv g(z). \)

By studying the above theorem, one may ask whether the conclusion of Theorem C still holds or not if the condition \( E(a_{1}, f) = E(a_{1}, g) \) is weakened to \( E(a_{1}, f) \cap G = E(a_{1}, g) \cap G \), where \( G \subseteq \mathbb{C} \) is a set such that \( \text{div}_{f-a_{1}}(z) \neq \text{div}_{g-a_{1}}(z) \) for \( z \in G. \) Here we will use \( \text{div}_{f-a_{1}}(z) \) to denote the multiplicity of a zero \( z \) of \( f(z) \). (It is pointed out \( \text{div}_{f}(z) \) may be zero, which implies that \( z \) is not a zero of \( f(z) \)). We emphasize that the point \( z \) in \( G \) is counted \( \max(\text{div}_{f-a_{1}}(z), \text{div}_{g-a_{1}}(z)) \) times. Below, we also need the notation \( \overline{E}(a_{1}, f) \cap G = \overline{E}(a_{1}, g) \cap G_{1} \), where \( G_{1} \subseteq E(a_{1}, f) \cup E(a_{1}, g) \) is a set such that either \( \text{div}_{f-a_{1}}(z) = 0 \) or \( \text{div}_{g-a_{1}}(z) = 0 \) for \( z \in G_{1.} \) And the point \( z \) in \( G_{1} \) is also counted \( \max(\text{div}_{f-a_{1}}(z), \text{div}_{g-a_{1}}(z)) \) times.

We agree to say \( E(a_{1}, f) = E(a_{1}, g) \) (resp. \( \overline{E}(a_{1}, f) = \overline{E}(a_{1}, g) \)) allowed the exceptional set \( G \) (resp. \( G_{1} \)) if \( E(a_{1}, f) \cap G = E(a_{1}, g) \cap G \) (resp. \( \overline{E}(a_{1}, f) \cap G = \overline{E}(a_{1}, g) \cap G_{1} \)) holds. The size of the set \( G \) is measured by the function \( n(r, G) \), the number of these points in \( G \cap |z| < r \) counted with multiplicities. And denote by \( N(r, G) \) (resp. \( \overline{N}(r, G) \)) the counting function (resp. the reduced counting function) of the set \( G. \) In the paper, we pay attention to the above problem and give an affirmative answer to it. More specifically, we prove the following.

**Theorem 1.** Let \( f(z) \) and \( g(z) \) be two non-constant entire functions, and let \( c \in \mathbb{C}\{0\} \). Suppose that \( \mu(f) \neq 1, \rho_{2}(f) < 1, \) and \( f(z) = f(z + c) \) for all \( z \in \mathbb{C}. \) If \( f(z) \) and \( g(z) \) satisfy \( E(0, f(z)) = E(0, g(z)) \) except for a possible set \( G_{1} \) and \( \overline{E}(1, f(z)) = \overline{E}(1, g(z)) \) except for a possible set \( G_{2}, \) where \( N(r, G_{i}) = O(r^{\lambda}(r)), (i = 1, 2) \) and \( \lambda < 1 \) is a constant, then \( f(z) \equiv g(z). \)

As a matter of fact, we get a more general result, and Theorem 1 is a special case of it.

**Theorem 2.** Let \( f(z) \) and \( g(z) \) be two non-constant meromorphic functions such that \( N(r, f) = O(r^{\lambda}), N(r, g) = O(r^{\lambda}), \) where \( \lambda < 1 \) is a constant, and let \( c \in \mathbb{C}\{0\} \). Suppose that \( \mu(f) \neq 1, \rho_{2}(f) < 1, \) and \( f(z) = f(z + c) \) for all \( z \in \mathbb{C}. \) If \( f(z) \) and \( g(z) \) satisfy \( E(0, f(z)) = E(0, g(z)) \) except for a possible set \( G_{1} \) and \( \overline{E}(1, f(z)) = \overline{E}(1, g(z)) \) except for a possible set \( G_{2}, \) where \( N(r, G_{i}) = O(r^{\lambda}(r)), (i = 1, 2) \), then \( f(z) \equiv g(z). \)

Clearly, Theorem 1 and 2 are generalizations of Theorem C. In order to prove the above theorems, we...
need the following theorem, which is of its own interest.

**Theorem 3.** Let $f(z)$ and $f(z+c)$ be two non-constant meromorphic functions of $\rho_2(f) < 1$ and $N(r, f) = S(r, f)$. If $f(z)$ and $f(z + c)$ satisfy $E(0, f(z)) \subseteq E(0, f(z + c))$ except for a possible set $G_1$, then $f(z) = f(z + c)$.

**Remark 1.** The condition $E(0, f(z)) \subseteq E(0, f(z + c))$ except for a possible set $G_1$ should be understood as above, where $G_1 \subseteq E(0, f(z))$ is a set such that $\text{div}_f(z) > \text{div}_f(z)$ for $z \in G_1$. And the point $z$ in $G_1$ is counted $\text{div}_f(z)$ times. We emphasise that the conclusion of Theorem 3 is still valid if the values $0, 1$ are replaced by two distinct periodic functions $a_1$ and $a_2$ with a period of $c$ and $T(r, a_i) = S(r, f)$. In fact, we only need to make the transformation $f(z) = f(z + \alpha)$.

**Remark 2.** There are many results which are related with Theorem 3. It was Heittokangas et. al. in [13] who firstly studied the uniqueness problem of $f(z)$ and $f(z + c)$ when they shared three distinct functions $a_i$ ($i = 1, 2, 3$) with period $c$, and $T(r, a_i) = S(r, f)$. Later on, Heittokangas et. al. [12] improved the uniqueness result by replacing the condition “3CM” with “2CM + 1IM”. Recently, Chen in [6] further generalized the above theorems with the idea of partially sharing values. We say $f(z)$ and $f(z + c)$ partially share 1 CM if $E(1, f(z)) \subseteq E(1, f(z + c))$. Clearly, Theorem 3 is an improvement of Chen’s result in some sense.

Before to proceed, we spare the reader for a moment and assume his/her familiarity with the basics of Nevanlinna’s theory of meromorphic functions in $\mathbb{C}$ such as the first and second fundamental theorems, and the usual notations such as the characteristic function $T(r, f)$, the proximity function $m(r, f)$ and the counting function $N(r, f)$. $S(r, f)$ denotes any quantity satisfying $S(r, f) = o(T(r, f))$ as $r \rightarrow \infty$, except possibly on a set of finite logarithmic measure - not necessarily the same at each occurrence (see e.g. [17, 19, 21]). We also need the following definition.

**Definition 1.1** The order $\rho(f)$, hyper-order $\rho_2(f)$, lower order $\mu(f)$ and low hyper-order $\mu_2(f)$ of the meromorphic function $f(z)$ are defined in turn as follows:

$$
\rho(f) = \lim_{r \to \infty} \frac{\log T(r, f)}{\log r}, \quad \rho_2(f) = \lim_{r \to \infty} \frac{\log \log T(r, f)}{\log r},
$$

$$
\mu(f) = \lim_{r \to \infty} \inf \frac{\log T(r, f)}{\log r}, \quad \mu_2(f) = \lim_{r \to \infty} \inf \frac{\log \log T(r, f)}{\log r}.
$$

**Proof of Theorem 3.** The proof is based on the idea of Chen in [6]. For the convenience of the reader, we present our proof in all detail. On the contrary, suppose that $f(z + c) \neq f(z)$. We below derive a contradiction. Set

$$
\frac{f(z + c)}{f(z)} = H.
$$

(1)

If $H \equiv 1$, then $f(z + c) = f(z)$, a contradiction. So, $H \neq 1$. By the logarithmic derivative lemma, one has

$$
m(r, H) = m(r, \frac{f(z + c)}{f(z)}) = S(r, f).
$$

(2)

Moreover, by the condition that $E(0, f(z)) \subseteq E(0, f(z + c))$ except for a possible set $G_1$, one has

$$
N(r, H) \leq N(r, G_1) + N(r, f(z + c)) \leq N(r, G_1) + N(r, f(z)) + S(r, f) = S(r, f),
$$

(3)
since \( N(r, f(z+c)) \leq N(r, f(z)) + S(r, f) \) if \( \rho_2(f) < 1 \), which can be seen in [16, Lemma 8.3]. Therefore, combining (2) and (3) yields that \( T(r, H) = m(r, H) + N(r, H) = S(r, f) \). Further, the assumption that \( \overline{E}(1, f(z)) \subset \overline{E}(1, f(z+c)) \) except for a possible set \( G_2 \) implies that

\[
\overline{N}(r, \frac{1}{f(z)-1}) \leq \overline{N}(r, G_2) + \overline{N}(r, \frac{1}{H(z)-1}) \leq \overline{N}(r, G_2) + T(r, H) \leq T(r, H(z)) + S(r, f) = S(r, f). \tag{4}
\]

By using the fact \( \overline{N}(r, \frac{1}{f(z) - r}) \leq \overline{N}(r, \frac{1}{f(z) + c}) + S(r, f) \) in [16, Lemma 8.3], we have

\[
\overline{N}(r, \frac{1}{f(z+c)-1}) \leq \overline{N}(r, \frac{1}{f(z)-1}) + S(r, f). \tag{5}
\]

Rewrite (1) to

\[
f(z) - 1 = H(f(z) - \frac{1}{H}).
\]

This means

\[
\overline{N}(r, \frac{1}{f(z) - r}) = \overline{N}(r, \frac{1}{f(z) - 1}) + S(r, f). \tag{6}
\]

Formulas (5) and (6) illustrate that

\[
\overline{N}(r, \frac{1}{f(z) - r}) = S(r, f).
\]

According to the second fundamental theorem, one has that

\[
T(r, f(z)) \leq \overline{N}(r, f(z)) + \overline{N}(r, \frac{1}{f(z) - 1}) + \overline{N}(r, \frac{1}{f(z) - H}) + S(r, f) \leq S(r, f),
\]

which is impossible. So \( f(z + c) \equiv f(z) \).

Thus, the proof is finished.

To end this section, we give another proof of Theorem 3, which may be a little complicated. But, it has its own interest. We firstly introduce the following auxiliary function, which can be found in [7].

\[
\phi = [f(z) - f(z + c)] \left\{ \frac{f'(z)}{f(z)(f(z) - 1)} - \frac{f'(z + c)}{f(z + c)(f(z + c) - 1)} \right\}. \tag{7}
\]

Suppose that \( \phi \neq 0 \). By the logarithmic derivative lemma again, we can obtain

\[
m(r, \phi) = m(r, (f(z) - f(z + c)(\frac{f'(z)}{f(z)(f(z) - 1)} - \frac{f'(z + c)}{f(z + c)(f(z + c) - 1)})) \]
\]
\[
\leq m(r, (f(z) - f(z + c))f'(z) \frac{f(z)}{f(z)(f(z) - 1)}) + m(r, (f(z) - f(z + c))f'(z + c) \frac{f(z)}{f(z + c)(f(z + c) - 1)}) + O(1) \]
\]
\[
\leq m(r, (f(z) - f(z + c)) \frac{f(z)}{f(z)} + m(r, \frac{f'(z)}{f(z) - 1}) + m(r, \frac{f'(z + c)}{f(z + c) - 1}) + O(1) = S(r, f). \tag{8}
\]

According to (7), we can get two properties of \( \phi \) by simple calculation, which can be found in [7].
Property 1. For $\eta_0 \in \mathbb{C}$, if $\eta_0$ is a zero of both $f(z)$ and $f(z+c)$ with multiplicity $p$, then $\eta_0$ is a zero of $\phi$ with multiplicity at least $p$;

Property 2. For $\eta_1 \in \mathbb{C}$, if $f(\eta_1) = f(\eta_1 + c) = 1$, then $\phi(\eta_1) \neq \infty$.

Now, we define some sets as follows.

$$E_1 = \{z : f(z) = 0, z \notin G_1\}, \quad E_2 = \{z : f(z) = 0, z \in G_1\},$$
$$E_3 = E(0, f(z+c)) \setminus E_1,$$

counting multiplicities.

By [Lemma 8.3] in [16] again and the condition that $E(0, f(z)) \subset E(0, f(z+c))$ except for a possible set $G_1$, we have

$$N(r, \frac{1}{f(z+c)}) = N(r, E_1) + N(r, E_3)$$
$$\leq N(r, \frac{1}{f(z)}) + S(r, f) = N(r, E_1) + N(r, E_2) + S(r, f)$$
$$\leq N(r, E_1) + N(r, G_1) + S(r, f) = N(r, E_1) + S(r, f),$$

which implies that $N(r, E_3) = S(r, f)$. Set

$$\alpha_1 = \{z : f(z) = 1, z \notin G_2\} \quad \alpha_2 = \{z : f(z) = 1, z \in G_2\},$$
$$\alpha_3 = E(1, f(z+c)) \setminus \alpha_1,$$

ignoring multiplicities.

The similar proceed leads that $N(r, \alpha_3) = S(r, f)$. Therefore, all the above discussions yields that

$$N(r, \phi) \leq N(r, f) + N(r, f(z+c)) + N(r, G_1) + N(r, G_2)$$
$$+ \overline{N}(r, \alpha_3) + \overline{N}(r, E_3) = S(r, f). \quad (9)$$

From (8) and (9), we can get $T(r, \phi) = m(r, \phi) + N(r, \phi) = S(r, f)$.

Moreover, the property 1 shows that

$$N(r, \frac{1}{f(z)}) \leq N(r, G_1) + N(r, \frac{1}{\phi}) \leq T(r, \phi) + S(r, f) = S(r, f). \quad (10)$$

From (4), (10) and $N(r, f) = S(r, f)$, we can deduced by the second fundamental theorem that

$$T(r, f(z)) \leq \overline{N}(r, \frac{1}{f(z)-1}) + \overline{N}(r, \frac{1}{f(z)}) + \overline{N}(r, f(z)) + S(r, f) = S(r, f),$$

which is a contradiction. Therefore, $\phi = 0$ and

$$\frac{f'(z)}{f(z)(f(z)-1)} = \frac{f'(z+c)}{f(z+c)(f(z+c)-1)}.$$

We next prove that $f(z)$ and $f(z+c)$ share 0 CM. Suppose that $\eta_0$ is a zero of $f(z)$ of multiplicity $p$. Then, the above equation yields that $\eta_0$ must be a zero of $(f(z)+c)$ or $(f(z)+1)-1$. Suppose $\eta_0$ is a zero of $(f(z)+c)-1$ of multiplicity $q$. Then, the Laurent expansions of $f(z)$ and $(f(z)+c)-1$ at $\eta_0$ are as follows.

$$f(z) = s_p(z-\eta_0)^p + s_{p+1}(z-\eta_0)^{p+1} + s_{p+2}(z-\eta_0)^{p+2} + \cdots, \quad (12)$$
$$f(z+c) - 1 = t_q(z-\eta_0)^q + t_{q+1}(z-\eta_0)^{q+1} + t_{q+2}(z-\eta_0)^{q+2} + \cdots, \quad (13)$$

where $s_i$ ($i = p, p+1, \cdots$) and $t_i$ ($i = q, q+1, \cdots$) are finite complex numbers with $s_p \neq 0$ and $t_q \neq 0$. Further, we get

$$f'(z) = ps_p(z-\eta_0)^{p-1} + (p+1)s_{p+1}(z-\eta_0)^p + (p+2)s_{p+2}(z-\eta_0)^{p+1} + \cdots, \quad (14)$$
Lemma 1. Let $f$ be a meromorphic function of hyper order $\rho_2 < 1$, and \( \eta \in \mathbb{C} \). Then for each \( \varepsilon > 0 \), we have

\[
m(r, \frac{f(z + \eta)}{f(z)}) = o\left(\frac{T(r, f)}{r^{1-\rho_2-\varepsilon}}\right) = S(r, f),
\]

for all \( r \) outside of a set of finite logarithmic measure.

Lemma 2. Let \( g \) be a non-constant meromorphic function in the plane of order less than 1, and let \( h > 0 \). Then there exists an \( \varepsilon \)-set \( E \) such that

\[
\frac{g(z + \eta)}{g(z)} \rightarrow 1, \text{ as } z \rightarrow \infty \text{ in } \mathbb{C} \setminus E,
\]

uniformly in \( \eta \) for \( |\eta| < h \).

Proof of Theorem 2 The proof is based on the ideas in [5, 7]. On the contrary, suppose that \( f(z) \equiv g(z) \). We below derive a contradiction. Note that \( f(z) \) is a non-constant periodic meromorphic function. Then

\[
f'(z + c) = qt^q(z - \eta_0)^{q-1} + (q + 1)t_{q+1}(z - \eta_0)^q + (q + 2)t_{q+2}(z - \eta_0)^{q+1} + \cdots,
\]

Combining (12) and (14) yields that

\[
\frac{f'(z)}{f(z)(f(z) - 1)} = \frac{1}{(0 - 1)} \cdot \frac{ps_p(z - \eta_0)^{p-1} + (p + 1)s_{p+1}(z - \eta_0)^p + (p + 2)s_{p+2}(z - \eta_0)^{p+1} + \cdots}{s_p(z - \eta_0)^p + s_{p+1}(z - \eta_0)^{p+1} + s_{p+2}(z - \eta_0)^{p+2} + \cdots}
\]

\[
= \frac{p}{(0 - 1)(z - \eta_0)} + \frac{s_{p+1}}{s_p(0 - 1)} + O(z - \eta_0).
\]

On the other hand, by (13) and (15) we get

\[
\frac{f'(z + c)}{f(z + c)(f(z + c) - 1)} = \frac{1}{(1 - 0)} \cdot \frac{qt^q(z - \eta_0)^{q-1} + (q + 1)t_{q+1}(z - \eta_0)^q + (q + 2)t_{q+2}(z - \eta_0)^{q+1} + \cdots}{t_q(z - \eta_0)^q + t_{q+1}(z - \eta_0)^{q+1} + t_{q+2}(z - \eta_0)^{q+2} + \cdots}
\]

\[
= \frac{q}{(1 - 0)(z - \eta_0)} + \frac{t_{q+1}}{t_q(1 - 0)} + O(z - \eta_0).
\]

Combining (16) and (17) yields \( -p = q \), which is impossible. So, \( \eta_0 \) must be a zero of \( f(z + c) \). Then, repeating the above argument can show that the multiplicity of \( f(z + c) \) at the point \( \eta_0 \) is \( p \), which implies that \( E(0, f(z)) \subseteq E(0, f(z + c)) \). Similarly, one can obtain \( E(0, f(z + c)) \subseteq E(0, f(z)) \). Therefore, \( f(z) \) and \( f(z + c) \) share 0 CM. Furthermore, we can derive that \( f(z) \) and \( f(z + c) \) share \( 1, \infty \) CM. We omit the proof here. Then, from [13, Theorem 2.1], we can show that \( f(z) \equiv f(z + c) \), a contradiction.

Thus, we finish the proof of Theorem 3.

2. Proof of Theorem 2

In this section, we shall prove the theorem 2. Before to its proof, we first give the following results, where the first one is Theorem 5.1 of Halburd-Korhonen-Tohge in [16], the second one is Lemma 3.3 of Bergweiler and Langley in [2].

Lemma 1. Let \( f \) be a meromorphic function of of hyper order \( \rho_2 < 1 \), and \( \eta \in \mathbb{C} \). Then for each \( \varepsilon > 0 \), we have

\[
m(r, \frac{f(z + \eta)}{f(z)}) = o\left(\frac{T(r, f)}{r^{1-\rho_2-\varepsilon}}\right) = S(r, f),
\]

for all \( r \) outside of a set of finite logarithmic measure.

Lemma 2. Let \( g \) be a non-constant meromorphic function in the plane of order less than 1, and let \( h > 0 \). Then there exists an \( \varepsilon \)-set \( E \) such that

\[
\frac{g(z + \eta)}{g(z)} \rightarrow 1, \text{ as } z \rightarrow \infty \text{ in } \mathbb{C} \setminus E,
\]

uniformly in \( \eta \) for \( |\eta| < h \).
\(\mu(f) \geq 1\). The fact can be found in [21, Lemma 5.1]. Together with \(N(r, f) = O(r^3)\), one has \(N(r, f) = S(r, f)\).

By the second fundamental theorem and the assumptions of Theorem 2, we have

\[
T(r, f) \leq N(r, \frac{1}{f}) + N(r, \frac{1}{f-1}) + N(r, f) + S(r, f)
\]

\[
= N(r, \frac{1}{g}) + N(r, \frac{1}{g-1}) + N(r, G_1) + N(r, G_2) + S(r, f)
\]

\[
\leq T(r, \frac{1}{g}) + T(r, \frac{1}{g-1}) + S(r, f)
\]

\[
= 2T(r, g) + S(r, f) \quad (r \to \infty, r \not\in E_0, \, \text{mes}E_0 < \infty).
\]  

Similarly, one has that

\[
T(r, g) \leq 2T(r, f) + S(r, g) \quad (r \to \infty, r \not\in E_1, \, \text{mes}E_1 < \infty).
\]  

Combining (18) and (19) yields

\[
1 < \mu(g) = \mu(f) \leq \rho(g) = \rho(f), \quad \rho_2(g) = \rho_2(f) < 1.
\]  

For convenience, we set \(S(r) := S(r, f) = S(r, g)\). By Hadamard factorization theorem, we can assume that

\[
\frac{f(z)}{g(z)} = e^{\pi_1(z)} e^{\alpha(z)} = P(z)e^{\alpha(z)},
\]

where \(k\) is an integer, \(\alpha(z)\) is an entire function, and \(\pi_1(z), \pi_2(z)\) are the canonical products of \(\frac{f(z)}{g(z)}\) formed with the non-null zeros and poles of \(f(z)\) and \(g(z)\), respectively. Obviously, by (21), one has

\[
\frac{f(z + c)}{g(z + c)} = (z + c)\frac{\pi_1(z + c)}{\pi_2(z + c)} e^{\alpha(z+c)} = P(z + c)e^{\alpha(z+c)}.
\]  

We claim that \(g(z) \equiv g(z + c)\), which implies that \(g\) is also a periodic function with period \(c\). Observe that \(E(0, f(z)) = E(0, g(z))\) except for a possible set \(G_1\) with \(N(r, G_1) = O(r^k)\). So, there exists a set \(G_2\) such that \(N(r, G_2) = O(r^3)\) and \(E(0, f(z + c)) = E(0, g(z + c))\) except for a possible set \(G_3\). In view of the periodic function \(f(z)\), one has \(E(0, f(z)) = E(0, f(z + c))\). All the above discussion shows that \(E(0, g(z)) = E(0, g(z + c))\) except for a possible set \(G_4 = G_1 \cup G_3\). Clearly, \(N(r, G_4) = O(r^k)\). Applying the same argument to the set of \(E(1, g(z))\) and \(E(1, g(z + c))\), one obtains that \(E(0, g(z)) = E(0, g(z + c))\) except for a possible set \(G_5\) with \(N(r, G_5) = O(r^k)\). Plus the fact \(N(r, g) = O(r^k)\), we see that the function \(g(z)\) and \(g(z + c)\) satisfy all the conditions of Theorem 3, which implies that \(g(z) \equiv g(z + c)\) and the claim is right. Furthermore, combining (21) and (22) yields that

\[
e^{\alpha(z) - \alpha(z+c)} = \frac{P(z + c)}{P(z)}.
\]

By the well-know result due to Borel (see [21, Theorem 2.3]), we know that the order \(\rho(\pi_i)\) of \(\pi_i(z)\) \((j = 1, 2)\) is equal to the exponent of convergence \(\lambda(\pi_i)\) of the zeros of \(\pi_i(z)\) \((j = 1, 2)\). Again from (21), we see that all the zeros of \(\pi_1\) (resp. \(\pi_2\)) come from the points of \(G_1\) and the poles of \(g(z)\) (resp \(f(z)\)). Thus, we can deduce that

\[
\rho(\pi_1) = \lambda(\pi_1) = \limsup_{r \to \infty} \frac{\log N(r, \frac{1}{\pi_1})}{\log r} = \limsup_{r \to \infty} \frac{\log N(r, g) + N(r, G_1)}{\log r} \leq \lambda < 1,
\]

\[
\rho(\pi_2) = \lambda(\pi_2) = \limsup_{r \to \infty} \frac{\log N(r, \frac{1}{\pi_2})}{\log r} = \limsup_{r \to \infty} \frac{\log N(r, f) + N(r, G_1)}{\log r} \leq \lambda < 1.
\]
The form \( P(z) = e^{-\frac{\pi i (z)}{\pi + \pi}} \) yields that \( p(P(z)) < 1 \). Together with Lemma 1, we get
\[
T(r, e^{\alpha(z) - \alpha(z + c)}) = m(r, e^{\alpha(z) - \alpha(z + c)}) = m(r, \frac{P(z + c)}{P(z)}) = O(r^{2P - 1 + c}) = O(r^c),
\]
which implies that \( \alpha(z) - \alpha(z + c) \) must be a constant. Let \( \alpha(z) - \alpha(z + c) \equiv h \) for some constant \( h \in \mathbb{C} \). Then
\[
e^h = \frac{P(z + c)}{P(z)},
\]
and \( \alpha'(z) - \alpha'(z + c) \equiv 0 \). Consequently \( \alpha'(z) \) is a periodic function with period \( c \). Suppose that \( \alpha'(z) \) is not constant. Then, \( \rho(\alpha(z)) = \rho(\alpha'(z)) \geq 1 \). On the other hand, by (21), we have \( \rho(\alpha(z)) = \rho(\alpha'(z)) \leq \rho(f) < 1 \), a contradiction. Therefore, \( \alpha'(z) \) is constant. Then, \( \alpha(z) \) is a periodic function, say \( \alpha(z) = az + b \) with constants \( a, b \in \mathbb{C} \). In view of \( \rho(P(z)) < 1 \) and Lemma 2, there exists a set \( E \) of finite logarithmic measure such that for \( |z| = r \notin E \),
\[
e^h = \frac{P(z + c)}{P(z)} \to 1, \text{ as } |z| \to \infty.
\]
Thus \( e^h = 1 \) and \( P(z) = P(z + c) \). The fact \( \rho(P(z)) < 1 \) forces that \( P \) is a constant, say \( A \). We rewrite (21) as
\[
\frac{f(z)}{g(z)} = Ae^{\alpha(z)} = Ae^{cz+b}.
\] (23)

In the following, we will prove that
\[
N(r, \frac{1}{f-1}) = N(r, \frac{1}{g-1}) = O(r).
\] (24)

We consider into two cases.

Case 1. \( a = 0 \).

Then, \( \frac{f(z)}{g(z)} = A^e \) is a constant. If there exists a point \( z_0 \) such that \( f(z_0) = g(z_0) = 1 \), then substituting \( z_0 \) into the above equation leads to \( f(z) \equiv g(z) \), a contradiction. Thus, \( f - 1 \) and \( g - 1 \) has no common zeros. Therefore, \( E(1, f) \subseteq G_2 \) and \( E(1, g) \subseteq G_2 \), which shows that
\[
N(r, \frac{1}{f-1}) \leq N(r, G_2) = O(r^p) = O(r), \quad N(r, \frac{1}{g-1}) \leq N(r, G_2) = O(r^q) = O(r).
\]

Case 2. \( a \neq 0 \).

In this case, we will employ a result of Chen in [5], which is stated as follows.

**Proposition.** Suppose that \( f(z) = f(z + c), g(z) = g(z + c) \) and \( \frac{f(z)}{g(z)} = Ae^{cz+b} \), where \( a \neq 0 \) and \( b \) are constant. If the point \( a_0 \) is common zero of \( f - 1 \) and \( g - 1 \) with multiplicities \( p \) and \( q \), respectively, then there exists a positive integer \( M \) (which is independent of \( a_0 \)) such that \( p, q \leq M \).

Suppose that \( b_0 \) is common zero of \( f - 1 \) and \( g - 1 \), then \( Ae^{cz+b}|_{b_0} = 1 \). By the above proposition, one has
\[
N(r, \frac{1}{f-1}) \leq MN(r, \frac{E(1, f)}{G_2}) + N(r, G_2) \leq MN(r, \frac{1}{Ae^{cz+b} - 1}) + O(r^p) = O(r).
\]

Similarly, we can deduce \( N(r, \frac{1}{g-1}) = O(r) \). From the cases 1 and 2, we prove the formula (24) holds. In addition, we set
\[
\frac{f(z) - 1}{g(z) - 1} = \frac{\pi_3(z)}{\pi_4(z)} = Q(z) = \pi_3(z) \pi_4(z),
\] (25)
where \( n \) is an integer, \( \beta(z) \) is an entire function, and \( \pi_3(z), \pi_4(z) \) are the canonical products of \( \frac{f(z)-1}{g(z)-1} \) formed with the non-null zeros and poles of \( f(z) - 1 \) and \( g(z) - 1 \), respectively.

It follows from (25) that
\[
\frac{f(z + c) - 1}{g(z + c) - 1} = (z + c)^n \frac{\pi_3(z + c)}{\pi_4(z + c)} e^{\beta(z+c)} = Q(z + c) e^{\beta(z+c)}.
\]

Combining (25) and (26) yields
\[
e^{\beta(z)-\beta(z+c)} = \frac{Q(z + c)}{Q(z)}.
\]

Consequently, using the same argument as in the proof of \( \rho(P(z)) < 1 \), we have
\[
\rho(\pi_3) = \lambda(\pi_3) = \limsup_{r \to \infty} \frac{\log N(r, \frac{1}{\pi_3})}{\log r} \leq \limsup_{r \to \infty} \frac{\log[N(r, g) + N(r, \frac{1}{g-1})]}{\log r} \leq 1,
\]
\[
\rho(\pi_4) = \lambda(\pi_4) = \limsup_{r \to \infty} \frac{\log N(r, \frac{1}{\pi_4})}{\log r} \leq \limsup_{r \to \infty} \frac{\log[N(r, f) + N(r, \frac{1}{g-1})]}{\log r} \leq 1.
\]

The form \( Q(z) = z^{n+\frac{\pi_3(z)}{\pi_4(z)}} \) implies that \( \rho(Q(z)) \leq 1 \). The same proceed as above can show that \( \beta(z) = c_1 z + d \) with two constants \( c_1, d \). Further,
\[
\frac{f(z) - 1}{g(z) - 1} = Q(z) e^{c_1 z + d}.
\]

Combining (23) and (28) gives that
\[
f(z) = \frac{-Q(z)e^{c_1 z + d} + 1}{1 - Q(z)A^{-1}d(c-\beta)z + d - b}.
\]

Then it follows from (29) that
\[
\rho(f) \leq \max\{\rho(Q), \rho(e^{c_1 z + d}), \rho(e^{\beta(z) + d - b})\} \leq 1,
\]
which contradicts the fact \( \rho(f) \geq \mu(f) > 1 \).

Thus, the proof is finished.
